## 1 Introduction

This document describes the requirements of an OpenFlow Logical Switch. Additional information describing OpenFlow and Software Defined Networking is available on the Open Networking Foundation website (https://www.opennetworking.org/). This specification covers the components and the basic functions of the switch, and the OpenFlow switch protocol to manage an OpenFlow switch from a remote OpenFlow controller.

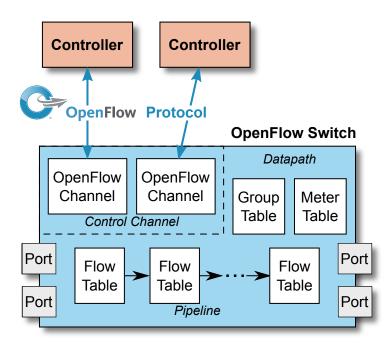

Figure 1: Main components of an OpenFlow switch.

## 2 Switch Components

An OpenFlow Logical Switch consists of one or more *flow tables* and a *group table*, which perform packet lookups and forwarding, and one or more *OpenFlow channels* to an external controller (Figure 1). The switch communicates with the controller and the controller manages the switch via the OpenFlow switch protocol.

Using the OpenFlow switch protocol, the controller can add, update, and delete *flow entries* in flow tables, both reactively (in response to packets) and proactively. Each flow table in the switch contains a set of flow entries; each flow entry consists of *match fields*, *counters*, and a set of *instructions* to apply to matching packets (see 5.2).

Matching starts at the first flow table and may continue to additional flow tables of the pipeline (see 5.1). Flow entries match packets in priority order, with the first matching entry in each table being used (see 5.3). If a matching entry is found, the instructions associated with the specific flow entry are executed (see 5.5). If no match is found in a flow table, the outcome depends on configuration of the

table-miss flow entry: for example, the packet may be forwarded to the controllers over the OpenFlow channel, dropped, or may continue to the next flow table (see 5.4).

Instructions associated with each flow entry either contain actions or modify pipeline processing (see 5.5). Actions included in instructions describe packet forwarding, packet modification and group table processing. Pipeline processing instructions allow packets to be sent to subsequent tables for further processing and allow information, in the form of metadata, to be communicated between tables. Table pipeline processing stops when the instruction set associated with a matching flow entry does not specify a next table; at this point the packet is usually modified and forwarded (see 5.6).

Flow entries may forward to a *port*. This is usually a physical port, but it may also be a logical port defined by the switch or a reserved port defined by this specification (see 4.1). Reserved ports may specify generic forwarding actions such as sending to the controller, flooding, or forwarding using non-OpenFlow methods, such as "normal" switch processing (see 4.5), while switch-defined logical ports may specify link aggregation groups, tunnels or loopback interfaces (see 4.4).

Actions associated with flow entries may also direct packets to a group, which specifies additional processing (see 5.10). Groups represent sets of actions for flooding, as well as more complex forwarding semantics (e.g. multipath, fast reroute, and link aggregation). As a general layer of indirection, groups also enable multiple flow entries to forward to a single identifier (e.g. IP forwarding to a common next hop). This abstraction allows common output actions across flow entries to be changed efficiently.

The group table contains group entries; each group entry contains a list of action buckets with specific semantics dependent on group type (see 5.10.1). The actions in one or more action buckets are applied to packets sent to the group.

Switch designers are free to implement the internals in any way convenient, provided that correct match and instruction semantics are preserved. For example, while a flow entry may use an all group to forward to multiple ports, a switch designer may choose to implement this as a single bitmask within the hardware forwarding table. Another example is matching; the pipeline exposed by an OpenFlow switch may be physically implemented with a different number of hardware tables.

## 3 Glossary

This section describes key OpenFlow specification terms. Most terms are specific to this specification.

- Action: an operation that forwards the packet to a port, modifies the packet (such as decrementing the TTL field) or changes its state (such as associating it with a queue). Most actions include parameters, for example a set-field action includes a field type and field value. Actions may be specified as part of the instruction set associated with a flow entry or in an action bucket associated with a group entry. Actions may be accumulated in the Action Set of the packet or applied immediately to the packet (see 5.8).
- List of Actions: a list of actions included in a flow entry in the *Apply-Actions* instruction or in a packet-out message that are executed immediately in the list order (see 5.7). Actions in a list can be duplicated, their effects are cumulative.

- Set of Actions: a set of actions included in a flow entry in the *Write-Actions* instruction that are added to the action set, or in a group action-bucket that are executed in action-set order (see 5.6). Actions in a set can occur only once.
- Action Bucket: a set of actions in a group. The group will select one or more buckets for each packet.
- Action Set: a set of actions associated with the packet that are accumulated while the packet is processed by each table and that are executed in specified order when the instruction set terminates pipeline processing (see 5.6).
- Byte: an 8-bit octet.
- Connection: a network connection that carry OpenFlow messages between a switch and a controller, it may be implemented using various network transport protocols (see 6.3). An OpenFlow channel has a main connection, and optionally a number of auxiliary connections (see 6.3.7).
- Control Channel: The aggregation of components of an OpenFlow logical switch that manage communication with controllers. The control channel includes one OpenFlow channel per OpenFlow controller.
- Controller: see OpenFlow controller.
- Counter: counters are the main element of OpenFlow statistics and accumulated at various specific points of the pipeline, such as on a port or on a flow entry (see 5.9). Counters typically count the number of packets and bytes passing through an OpenFlow element, however other counters types are also defined.
- Datapath: the aggregation of components of an OpenFlow logical switch that are directly involved in traffic processing and forwarding. The datapath includes the pipeline of flow tables, the group table and the ports.
- Flow Entry: an element in a flow table used to match and process packets. It contains a set of match fields for matching packets, a priority for matching precedence, a set of counters to track packets, and a set of instructions to apply (see 5.2).
- Flow Table: a stage of the pipeline. It contains flow entries.
- Forwarding: Deciding the output port or set of output ports for a packet, and transfering that packet to those output ports.
- **Group**: a list of action buckets and some means of choosing one or more of those buckets to apply on a per-packet basis (see 5.10).
- **Header**: control information embedded in a packet used by a switch to identify the packet and to inform the switch on how to process and forward the packet. The header typically includes various header fields to identify the source and destination of the packet, and how to interpret other headers and the payload.
- **Header Field**: a value from the packet header. The packet header is parsed to extract its header fields which are matched against corresponding match fields.
- **Hybrid**: integrate both OpenFlow operation and *normal* Ethernet switching operation (see 5.1).

- **Instruction**: instructions are attached to a flow entry and describe the OpenFlow processing that happens when a packet matches the flow entry. An instruction either modifies pipeline processing, such as directing the packet to another flow table, or contains a *set* of actions to add to the action set, or contains a *list* of actions to apply immediately to the packet (see 5.5).
- Instruction Set: a set of instructions attached to a flow entry in a flow table.
- Match Field: a part of a flow entry against which a packet is matched. Match fields can match the various packet header fields (see 7.2.3.8), the packet ingress port, the metadata value and other pipeline fields (see 7.2.3.9). A match field may be wildcarded (match any value) and in some cases bitmasked (match subset of bits).
- Matching: comparing the set of header fields and pipeline fields of a packet to the match fields of a flow entry (see 5.3).
- Metadata: a maskable register that is used to carry information from one table to the next.
- **Message**: OpenFlow protocol unit sent over an OpenFlow connection. May be a request, a reply, a control message or a status event.
- Meter: a switch element that can measure and control the rate of packets. The meter triggers a meter band if the packet rate or byte rate passing through the meter exceeds a predefined threshold (see 5.11). If the meter band drops the packet, it is called a **Rate Limiter**.
- **OpenFlow Channel**: interface between an OpenFlow switch and an OpenFlow controller, used by the controller to manage the switch.
- OpenFlow Controller: an entity interacting with the OpenFlow switch using the OpenFlow switch protocol. In most case, an OpenFlow Controller is software which controls many OpenFlow Logical Switches.
- **OpenFlow Logical Switch**: A set of OpenFlow resources that can be managed as a single entity, includes a datapath and a control channel.
- OpenFlow Protocol: The protocol defined by this specification. Also called OpenFlow Switch Protocol.
- OpenFlow Switch: See OpenFlow Logical Switch.
- Packet: a series of bytes comprising a header, a payload and optionally a trailer, in that order, and treated as a unit for purposes of processing and forwarding. The default packet type is Ethernet, other packet types are also supported (see 7.2.3.11).
- **Pipeline**: the set of linked flow tables that provide matching, forwarding, and packet modification in an OpenFlow switch (see 5.1).
- **Pipeline fields**: set of values attached to the packet during pipeline processing which are not header fields. Include the ingress port, the metadata value, the Tunnel-ID value and others (see 7.2.3.9).
- **Port**: where packets enter and exit the OpenFlow pipeline (see 4.1). May be a physical port, a logical port, or a reserved port defined by the OpenFlow switch protocol.
- Queue: Schedule packets according to their priority on an output port to provide Quality-of-Service (QoS).

- Switch: See OpenFlow Logical Switch.
- Tag: a header that can be inserted or removed from a packet via push and pop actions.
- Outermost Tag: the tag that appears closest to the beginning of a packet.

## 4 OpenFlow Ports

This section describes the OpenFlow port abstraction and the various types of OpenFlow ports supported by OpenFlow.

## 4.1 OpenFlow Ports

OpenFlow ports are the network interfaces for passing packets between OpenFlow processing and the rest of the network. OpenFlow switches connect logically to each other via their OpenFlow ports, a packet can be forwarded from one OpenFlow switch to another OpenFlow switch only via an output OpenFlow port on the first switch and an ingress OpenFlow port on the second switch.

An OpenFlow switch makes a number of OpenFlow ports available for OpenFlow processing. The set of OpenFlow ports may not be identical to the set of network interfaces provided by the switch hardware, some network interfaces may be disabled for OpenFlow, and the OpenFlow switch may define additional OpenFlow ports.

OpenFlow packets are received on an **ingress port** and processed by the OpenFlow pipeline (see 5.1) which may forward them to an **output port**. The packet ingress port is a property of the packet throughout the OpenFlow pipeline and represents the OpenFlow port on which the packet was received into the OpenFlow switch. The ingress port can be used when matching packets (see 5.3). The OpenFlow pipeline can decide to send the packet on an output port using the output action (see 5.8), which defines how the packet goes back to the network.

An OpenFlow switch must support three types of OpenFlow ports: *physical ports*, *logical ports* and *reserved ports*.

#### 4.2 Standard Ports

The OpenFlow **standard ports** are defined as physical ports, logical ports, and the LOCAL reserved port if supported (excluding other reserved ports).

Standard ports can be used as ingress and output ports, they can be used in groups (see 5.10), they have port counters (see 5.9) and they have state and configuration (see 7.2.1).

## 4.3 Physical Ports

The OpenFlow **physical ports** are switch defined ports that correspond to a hardware interface of the switch. For example, on an Ethernet switch, physical ports map one-to-one to the Ethernet interfaces.

In some deployments, the OpenFlow switch may be virtualised over the switch hardware. In those cases, an OpenFlow physical port may represent a virtual slice of the corresponding hardware interface of the switch.

## 4.4 Logical Ports

The OpenFlow logical ports are switch defined ports that don't correspond directly to a hardware interface of the switch. Logical ports are higher level abstractions that may be defined in the switch using non-OpenFlow methods (e.g. link aggregation groups, tunnels, loopback interfaces).

Logical ports may include packet encapsulation and may map to various physical ports. The processing done by the logical port is implementation dependant and must be transparent to OpenFlow processing, and those ports must interact with OpenFlow processing like OpenFlow physical ports.

The only differences between *physical ports* and *logical ports* is that a packet associated with a logical port may have an extra pipeline field called *Tunnel-ID* associated with it (see 7.2.3.9) and when a packet received on a logical port is sent to the controller, both its logical port and its underlying physical port are reported to the controller (see 7.4.1).

#### 4.5 Reserved Ports

The OpenFlow **reserved ports** are defined by this specification. They specify generic forwarding actions such as sending to the controller, flooding, or forwarding using non-OpenFlow methods, such as "normal" switch processing.

A switch is not required to support all reserved ports, just those marked "Required" below.

- Required: ALL: Represents all ports the switch can use for forwarding a specific packet. Can be used only as an output port. In that case a copy of the packet starts egress processing on all standard ports, excluding the packet ingress port and ports that are configured OFPPC\_NO\_FWD.
- Required: CONTROLLER: Represents the control channel with the OpenFlow controllers. Can be used as an ingress port or as an output port. When used as an output port, encapsulate the packet in a packet-in message and send it using the OpenFlow switch protocol (see 7.4.1). When used as an ingress port, this identifies a packet originating from the controller.
- Required: **TABLE:** Represents the start of the OpenFlow pipeline (see 5.1). This port is only valid in an output action in the list of actions of a *packet-out* message (see 7.3.6), and submits the packet to the first flow table so that the packet can be processed through the regular OpenFlow pipeline.
- Required: IN\_PORT: Represents the packet ingress port. Can be used only as an output port, send the packet out through its ingress port.

- Required: ANY: Special value used in some OpenFlow requests when no port is specified (i.e. port is wildcarded). Some OpenFlow requests contain a reference to a specific port that the request only applies to. Using ANY as the port number in these requests allows that request instance to apply to any and all ports. Can neither be used as an ingress port nor as an output port.
- Required: UNSET: Special value to specify the that output port has not been set in the Action-Set. Only used when trying to match the output port in the action set using the OXM\_OF\_ACTSET\_OUTPUT match field (see 7.2.3.7). Can neither be used as an ingress port nor as an output port.
- Optional: LOCAL: Represents the switch's local networking stack and its management stack. Can be used as an ingress port or as an output port. The local port enables remote entities to interact with the switch and its network services via the OpenFlow network, rather than via a separate control network. With a suitable set of default flow entries it can be used to implement an in-band controller connection.
- Optional: NORMAL: Represents forwarding using the traditional non-OpenFlow pipeline of the switch (see 5.1). Can be used only as an output port and processes the packet using the normal pipeline. In general will bridge or route the packet, however the actual result is implementation dependant. If the switch cannot forward packets from the OpenFlow pipeline to the normal pipeline, it must indicate that it does not support this action.
- Optional: **FLOOD:** Represents flooding using the traditional non-OpenFlow pipeline of the switch (see 5.1). Can be used only as an output port, actual result is implementation dependant. In general will send the packet out all standard ports, but not to the ingress port, nor ports that are in OFPPS\_BLOCKED state. The switch may also use the packet VLAN ID or other criteria to select which ports to use for flooding.

OpenFlow-only switches do not support the **NORMAL** port and **FLOOD** port, while OpenFlow-hybrid switches may support them (see 5.1). Forwarding packets to the **FLOOD** port depends on the switch implementation and configuration, while forwarding using a **group** of type all enables the controller to more flexibly implement flooding (see 5.10.1).

## 4.6 Port changes

A switch configuration, for example using the OpenFlow Configuration Protocol, may add or remove ports from the OpenFlow switch at any time. The switch may change the port state based on the underlying port mechanism, for example if the link is going down (see 7.2.1). The controller or a switch configuration may change the port configuration (see 7.2.1). Any such changes to port state or configuration must be communicated to the OpenFlow controller (see 7.4.3).

Port addition, modification or removal never changes the content of the flow tables, in particular flow entries referencing those ports are not modified or removed (flow entries may reference ports via the match or actions). Packet forwarded to non-existent ports are just dropped (see 5.6). Similarly, Port addition, modification and removal never changes the content of the group table, however the behaviour of some groups may change through liveness checking (see 6.7).

If a port is deleted and its port number is later reused for a different physical or logical port, any remaining flow entries or group entries still referencing that port number may be effectively re-targeted

to the new port, possibly with undesirable results. Therefore, when a port is deleted it is left to the controller to clean up any flow entries or group entries referencing that port, if needed.

## 4.7 Port recirculation

Logical ports can optionally be used to insert a network service or complex processing in the OpenFlow switch (see 4.4). Most often, packets sent to logical ports never return to the same OpenFlow switch, they are either consumed by the logical port or eventually sent over a physical port. In other cases, packets sent to a logical port are recirculated back to the OpenFlow switch after the logical port processing.

Packet recirculation via logical ports is optional, and OpenFlow supports multiple types of port recirculation. The simplest recirculation is when a packet sent on a logical port returns back into the switch via the same logical port. This could be used for a loopback or unidirectional packet processing. Recirculation can also happen between a port pair, in which a packet sent on a logical port returns back into the switch via the other logical port of the pair. This could be used to represent tunnel endpoints or bidirectional packet processing. A port property describes the recirculation relationship between ports (see 7.2.1.2).

A switch should protect itself from packet infinite loops when using port recirculation. This mechanism is implementation-specific and outside the scope of this specification. For example, the switch could attach an internal recirculation count to each packet, which is incremented for each recirculation, and the switch drops packets for which the counter is above a switch-defined threshold. Controllers are strongly encouraged to avoid generating combinations of flow entries that may yield recirculation loops.

Because of the wide range of possible processing, very little can be assumed about the packets recirculated back into the switch. Recirculated packets go back to the first flow table of the pipeline (see 5.1) and can be identified by their new input port. The packet headers may have changed, so the match fields are not guaranteed to be the same. The logical port may do packet fragmentation and reassembly, so the packets may not match one to one and may have different sizes.

The *Tunnel-ID* field and some other pipeline fields associated with the packet may optionally be preserved through the recirculation and available for matching when returning to the switch, the pipeline fields that are preserved are indicated via the port match field property (see 7.2.1.2). If a pipeline field is present in both the OFPPDPT\_PIPELINE\_OUTPUT property of the output port and the OFPPDPT\_PIPELINE\_INPUT property of the return port, then this pipeline field is preserved with the packet (its value must remain the same).

## 5 OpenFlow Tables

This section describes the components of flow tables and group tables, along with the mechanics of matching and action handling.

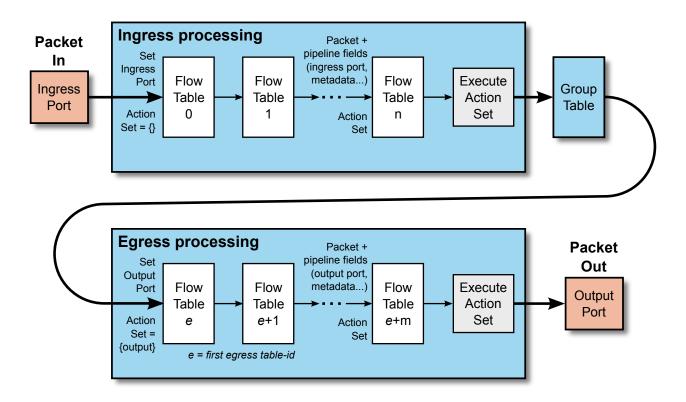

Figure 2: Packet flow through the processing pipeline.

## 5.1 Pipeline Processing

OpenFlow-compliant switches come in two types: *OpenFlow-only*, and *OpenFlow-hybrid*. **OpenFlow-only** switches support only OpenFlow operation, in those switches all packets are processed by the OpenFlow pipeline, and can not be processed otherwise.

OpenFlow-hybrid switches support both OpenFlow operation and normal Ethernet switching operation, i.e. traditional L2 Ethernet switching, VLAN isolation, L3 routing (IPv4 routing, IPv6 routing...), ACL and QoS processing. Those switches should provide a classification mechanism outside of OpenFlow that routes traffic to either the OpenFlow pipeline or the normal pipeline. For example, a switch may use the VLAN tag or input port of the packet to decide whether to process the packet using one pipeline or the other, or it may direct all packets to the OpenFlow pipeline. This classification mechanism is outside the scope of this specification. An OpenFlow-hybrid switch may also allow a packet to go from the OpenFlow pipeline to the normal pipeline through the NORMAL and FLOOD reserved ports (see 4.5).

The **OpenFlow pipeline** of every OpenFlow Logical Switch contains one or more flow tables, each flow table containing multiple flow entries. The OpenFlow pipeline processing defines how packets interact with those flow tables (see Figure 2). An OpenFlow switch is required to have at least one ingress flow table, and can optionally have more flow tables. An OpenFlow switch with only a single flow table is valid, in this case pipeline processing is greatly simplified.

The flow tables of an OpenFlow switch are sequentially numbered, starting at 0. Pipeline processing

happens in two stages, *ingress processing* and *egress processing*. The separation of the two stages is indicated by the first egress table (see 7.3.2), all tables with a number lower than the first egress table must be used as ingress tables, and no table with a number higher than or equal to the first egress table can be used as an ingress table.

Pipeline processing always starts with ingress processing at the first flow table: the packet must be first matched against flow entries of flow table 0 (see Figure 3). Other ingress flow tables may be used depending on the outcome of the match in the first table. If the outcome of ingress processing is to forward the packet to an output port, the OpenFlow switch may perform egress processing in the context of that output port. Egress processing is optional, a switch may not support any egress tables or may not be configured to use them. If no valid egress table is configured as the first egress table (see 7.3.2), the packet must be process by the output port, and in most case the packet is forwarded out of the switch. If a valid egress table is configured as the first egress table (see 7.3.2), the packet must be matched against flow entries of that flow table, and other egress flow tables may be used depending on the outcome of the match in that flow table.

When processed by a flow table, the packet is matched against the flow entries of the flow table to select a flow entry (see 5.3). If a flow entry is found, the instruction set included in that flow entry is executed. These instructions may explicitly direct the packet to another flow table (using the Goto-Table Instruction, see 5.5), where the same process is repeated again. A flow entry can only direct a packet to a flow table number which is greater than its own flow table number, in other words pipeline processing can only go forward and not backward. Obviously, the flow entries of the last table of a pipeline stage can not include the Goto-Table instruction. If the matching flow entry does not direct packets to another flow table, the current stage of pipeline processing stops at this table, the packet is processed with its associated action set and usually forwarded (see 5.6).

If a packet does not match a flow entry in a flow table, this is a table miss. The behavior on a table miss depends on the table configuration (see 5.4). The instructions included in the table-miss flow entry in the flow table can flexibly specify how to process unmatched packets, useful options include dropping them, passing them to another table or sending them to the controllers over the control channel via packet-in messages (see 6.1.2).

There are few cases where a packet is not fully processed by a flow entry and pipeline processing stops without processing the packet's action set or directing it to another table. If no table-miss flow entry is present, the packet is dropped (see 5.4). If an invalid TTL is found, the packet may be sent to the controller (see 5.8).

The OpenFlow pipeline and various OpenFlow operations process packets of a specific type in conformance with the specifications defined for that packet type, unless the present specification or the OpenFlow configuration specify otherwise. For example, the Ethernet header definition used by OpenFlow must conform to IEEE specifications, and the TCP/IP header definition used by OpenFlow must conform to RFC specifications. Additionally, packet reordering in an OpenFlow switch must conform to the requirements of IEEE specifications, provided that the packets are processed by the same flow entries, group buckets and meter bands.

## 5.1.1 Pipeline Consistency

The OpenFlow pipeline is an abstraction that is mapped to the actual hardware of the switch. In some cases, the OpenFlow switch is virtualised on the hardware, for example to support multiple OpenFlow switch instances or in the case of an hybrid switch. Even if the OpenFlow switch is not virtualised, the hardware typically will not correspond to the OpenFlow pipeline, for example if a flow table only supports Ethernet packets, non-Ethernet packets would have to be mapped to Ethernet. In another example some switches may carry VLAN information in some internal metadata while for the OpenFlow pipeline it is logically part of the packet. Some OpenFlow switches may define logical ports implementing complex encapsulations that extensively modify the packet headers. The consequence is that a packet on a link or in hardware may be mapped differently in the OpenFlow pipeline.

However, the OpenFlow pipeline expects that the mapping to the hardware is consistent, and that the OpenFlow pipeline behaves consistently. In particular, this is what is expected:

- Tables consistency: the packet must match in the same way in all the OpenFlow flow tables, and the only difference in matching must be due to the flow table content and explicit OpenFlow processing done by those flow tables. In particular, headers can not be transparently removed, added or changed between tables, unless explicitly specified by OpenFlow processing.
- Flow entry consistency: the way the actions of a flow entry apply to a packet must be consistent with the flow entry match. In particular, if a match field in the flow entry matches a specific packet header field, the corresponding set-field action in the flow entry must modify the same header field, unless explicit OpenFlow processing has modified the packet.
- **Group consistency**: the application of groups must be consistent with flow tables. In particular, actions of a group bucket must apply to the packet the same way as if they were in a flow table, the only difference must be due to explicit OpenFlow processing.
- Packet-in consistency: the packet embedded in the packet-in messages must be consistent with the OpenFlow flow tables. In particular, if the packet-in was generated directly by a flow entry, the packet received by the controller must match the flow entry that sent it to the controller.
- Packet-out consistency: the packet generated as the result of a packet-out request must be consistent with the OpenFlow flow tables and the packet-in process. In particular, if a packet received via a packet-in is is sent directly without modifications out a port via a packet-out, the packet on that port must be identical, as if the packet had been sent to that port instead of encapsulated in a packet-in. Similarly, if a packet-out is directed at flow tables, the flow entries must match the encapsulated packet as expected by the OpenFlow matching process.
- **Port consistency**: the ingress and egress processing of an OpenFlow port must be consistent with each other. In particular, if an OpenFlow packet is output on a port and generates a physical packet on a switch physical link, then if the reception by the switch of the same physical packet on the same link generates an OpenFlow packet on the same port, the OpenFlow packet must be identical.

## 5.2 Flow Tables and flow entries

A flow table consists of flow entries.

Match Fields	Priority	Counters	Instructions	Timeouts	Cookie	Flags	
--------------	----------	----------	--------------	----------	--------	-------	--

Table 1: Main components of a flow entry in a flow table.

Each flow table entry (see Table 1) contains:

- match fields: to match against packets. These consist of the ingress port and packet headers, and optionally other pipeline fields such as metadata specified by a previous table.
- **priority**: matching precedence of the flow entry.
- **counters**: updated when packets are matched.
- **instructions**: to modify the action set or pipeline processing.
- timeouts: maximum amount of time or idle time before flow is expired by the switch.
- **cookie**: opaque data value chosen by the controller. May be used by the controller to filter flow entries affected by flow statistics, flow modification and flow deletion requests. Not used when processing packets.
- flags: flags alter the way flow entries are managed, for example the flag OFPFF\_SEND\_FLOW\_REM triggers flow removed messages for that flow entry.

A flow table entry is identified by its match fields and priority: the match fields and priority taken together identify a unique flow entry in a specific flow table. The flow entry that wildcards all fields (all fields omitted) and has priority equal to 0 is called the table-miss flow entry (see 5.4).

A flow entry instruction may contain actions to be performed on the packet at some point of the pipeline (see 5.8). The *set-field* action may specify some header fields to rewrite. Each flow table may not support every match field, every instruction, every action or every set-field defined by this specification, and different flow tables of the switch may not support the same subset. The table features request enables the controller to discover what each table supports (see 7.3.5.18).

## 5.3 Matching

On receipt of a packet, an OpenFlow Switch performs the functions shown in Figure 3. The switch starts by performing a table lookup in the first flow table, and based on pipeline processing, may perform table lookups in other flow tables (see 5.1).

Packet match fields are extracted from the packet. Packet match fields used for table lookups depend on the packet type, and typically include various packet header fields, such as Ethernet source address or IPv4 destination address (see 7.2.3). In addition to packet headers, matches can also be performed against the ingress port, the metadata field and other pipeline fields. Metadata may be used to pass information between tables in a switch. The packet match fields represent the packet in its current state, if actions applied in a previous table using the *Apply-Actions* instruction changed the packet headers, those changes are reflected in the packet match fields.

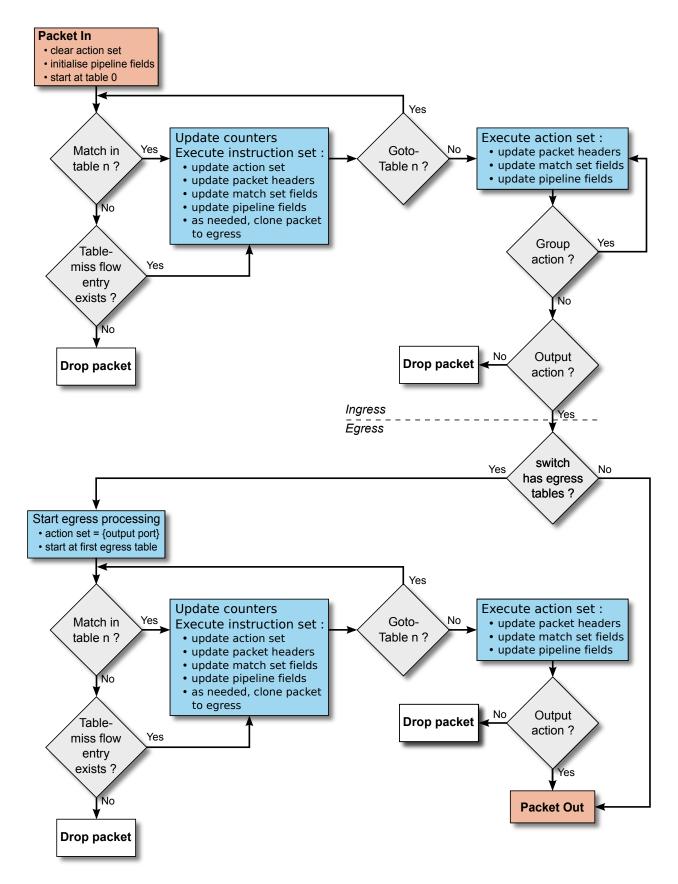

Figure 3: Simplified flowchart detailing packet flow through an OpenFlow switch.

A packet matches a flow table entry if the values in the packet match fields used for the lookup match those defined in the flow table entry. If a flow table entry field has a value of ANY (field omitted), it matches all possible values in the header. If the switch supports arbitrary bitmasks on specific match fields, these masks can more precisely specify matches.

The packet is matched against the table and *only* the highest priority flow entry that matches the packet must be selected. The counters associated with the selected flow entry must be updated and the instruction set included in the selected flow entry must be applied. If there are multiple matching flow entries with the same highest priority, the selected flow entry is explicitly undefined. This case can only arise when a controller writer never sets the OFPFF\_CHECK\_OVERLAP bit on flow mod messages and adds overlapping entries.

IP fragments must be reassembled before pipeline processing if the switch configuration contains the OFPC\_FRAG\_REASM flag (see 7.3.2).

This version of the specification does *not* define the expected behavior when a switch receives a malformed or corrupted packet.

## 5.4 Table-miss

Every flow table must support a table-miss flow entry to process table misses. The table-miss flow entry specifies how to process packets unmatched by other flow entries in the flow table (see 5.1), and may, for example, send packets to the controller, drop packets or direct packets to a subsequent table.

The table-miss flow entry is identified by its match and its priority (see 5.2), it wildcards all match fields (all fields omitted) and has the lowest priority (0). The match of the table-miss flow entry may fall outside the normal range of matches supported by a flow table, for example an exact match table would not support wildcards for other flow entries but must support the table-miss flow entry wildcarding all fields. The table-miss flow entry may not have the same capability as regular flow entry (see 7.3.5.18). The table-miss flow entry must support at least sending packets to the controller using the CONTROLLER reserved port (see 4.5) and dropping packets using the Clear-Actions instruction (see 5.5). Implementations are encouraged to support directing packets to a subsequent table when possible for compatibility with earlier versions of this specification.

The table-miss flow entry behaves in most ways like any other flow entry: it does not exist by default in a flow table, the controller may add it or remove it at any time (see 6.4), and it may expire (see 6.5). The table-miss flow entry matches packets in the table as expected from its set of match fields and priority (see 5.3): it matches packets unmatched by other flow entries in the flow table. The table-miss flow entry instructions are applied to packets matching the table-miss flow entry (see 5.5). If the table-miss flow entry directly sends packets to the controller using the CONTROLLER reserved port (see 4.5), the packet-in reason must identify a table-miss (see 7.4.1).

If the table-miss flow entry does not exist, by default packets unmatched by flow entries are dropped (discarded). A switch configuration, for example using the OpenFlow Configuration Protocol, may override this default and specify another behaviour.

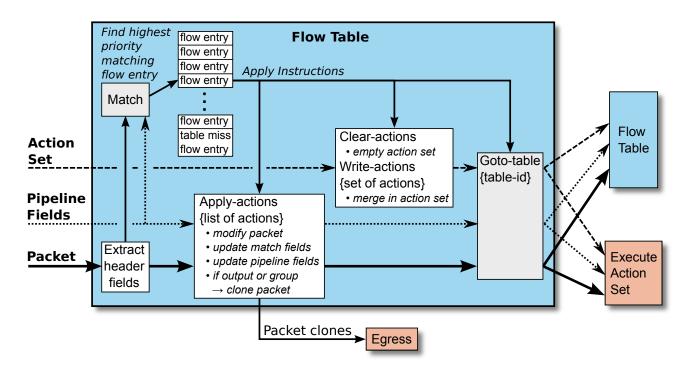

Figure 4: Matching and Instruction execution in a flow table.

## 5.5 Instructions

Each flow entry contains a set of instructions that are executed when a packet matches the entry. These instructions result in changes to the packet, action set and/or pipeline processing (see Figure 4).

A switch is not required to support all instruction types, just those marked "Required Instruction" below. The controller can also query the switch about which of the "Optional Instruction" types it supports.

- Optional Instruction: Apply-Actions action(s): Applies the specific action(s) immediately, without any change to the Action Set. This instruction may be used to modify the packet between two tables or to execute multiple actions of the same type. The actions are specified as a list of actions (see 5.7).
- Optional Instruction: Clear-Actions: Clears all the actions in the action set immediately.
- Required Instruction: Write-Actions action(s): Merges the specified set of action(s) into the current action set (see 5.6). If an action of the given type exists in the current set, overwrite it, otherwise add it. If a set-field action with a given field type exists in the current set, overwrite it, otherwise add it.
- Optional Instruction: Write-Metadata metadata / mask: Writes the masked metadata value into the metadata field. The mask specifies which bits of the metadata register should be modified (i.e. new\_metadata = old\_metadata & ~mask | value & mask).

- Optional Instruction: Stat-Trigger stat thresholds: Generate an event to the controller if some of the flow statistics cross one of the stat threshold values.
- Required Instruction: Goto-Table next-table-id: Indicates the next table in the processing pipeline. The table-id must be greater than the current table-id. The flow entries of the last table of the pipeline can not include this instruction (see 5.1). OpenFlow switches with only a single flow table are not required to implement this instruction.

The instruction set associated with a flow entry contains a maximum of one instruction of each type. The experimenter instructions are identified by their experimenter-id and experimenter-type, therefore the instruction set may contain a maximum of one experimenter instruction for each combination of experimenter-id and experimenter-type. The instructions of the set execute in the order specified by this above list. In practice, the only constraints are that the Clear-Actions instruction is executed before the Write-Actions instruction, the Apply-Actions is executed before the Write-Metadata and that Goto-Table is executed last.

A switch must reject a flow entry if it is unable to execute the instructions or part of the instructions associated with the flow entry. In this case, the switch must return the error message associated with the issue (see 7.5.4.4).

#### 5.6 Action Set

An action set is associated with each packet. This set is empty by default. A flow entry can modify the action set using a *Write-Action* instruction or a *Clear-Action* instruction associated with a particular match. The action set is carried between flow tables. When the instruction set of a flow entry does not contain a *Goto-Table* instruction, pipeline processing stops and the actions in the action set of the packet are executed (see Figure 3).

An action set contains a maximum of one action of each type. The set-field actions are identified by their destination field types, therefore the action set contains a maximum of one set-field action for each field type (i.e. multiple fields can be set, but each field can only be set once). The effect of copy-field actions in the action set is undefined due to race conditions, and therefore its implementation discouraged. The experimenter actions are identified by their experimenter-id and experimenter-type, therefore the action set may contain a maximum of one experimenter action for each combination of experimenter-id and experimenter-type. When an action of a specific type is added in the action set, if an action of the same type exist, it is overwritten by the later action. If multiple actions of the same type are required, e.g. pushing multiple MPLS labels or popping multiple MPLS labels, the Apply-Actions instruction should be used (see 5.7).

The action set for egress processing has one restriction, both the *output* action and the *group* action can not be added to the egress action-set. The action set for egress processing is initialised at the beginning of egress processing with an *output* action for the current output port, whereas the action set for ingress processing starts empty.

The actions in an action set are applied in the order specified below, regardless of the order that they were added to the set. If an action set contains a group action, the actions in the appropriate action bucket(s) of the group are also applied in the order specified below. The switch may support arbitrary action execution order through the list of actions of the Apply-Actions instruction.

- 1. copy TTL inwards: apply copy TTL inward actions to the packet
- 2. **pop**: apply all tag pop actions to the packet
- 3. push-MPLS: apply MPLS tag push action to the packet
- 4. push-PBB: apply PBB tag push action to the packet
- 5. **push-VLAN**: apply VLAN tag push action to the packet
- 6. copy TTL outwards: apply copy TTL outwards action to the packet
- 7. **decrement TTL**: apply decrement TTL action to the packet
- 8. set: apply all set-field actions to the packet
- 9. qos: apply all QoS actions, such as meter and set\_queue to the packet
- 10. **group**: if a group action is specified, apply the actions of the relevant group bucket(s) in the order specified by this list
- 11. **output**: if no group action is specified, forward the packet on the port specified by the output action

The *output* action in the action set is executed last. If both an *output* action and a *group* action are specified in an action set, the output action is ignored and the group action takes precedence. If no output action and no group action were specified in an action set, the packet is dropped. If no group action is specified and the output action references an non-existent port, the packet is dropped. The execution of groups is recursive if the switch supports it; a group bucket may specify another group, in which case the execution of actions traverses all the groups specified by the group configuration.

The *output* action is processed differently in ingress and egress (see 5.1). When the ingress action set contains an *output* action or a *group* action forwarding the packet to a port, the packet must start egress processing on that port (see 5.1). If the *output* action references the *ALL* reserved port, a clone (copy) of the packet start egress processing for each relevant port (see 4.5). When the egress action set contains an *output* action, the packet must exit egress processing and must be processed by the port, and in most cases it is forwarded out of the switch.

## 5.7 List of Actions

The Apply-Actions instruction and the Packet-out message include a list of actions. The semantics of the list of actions is identical to the OpenFlow 1.0 specification. The actions of a list of actions are executed in the order specified by the list, and are applied immediately to the packet.

The execution of a list of actions starts with the first action in the list and each action is executed on the packet in sequence. The effect of those actions is cumulative, if the list of actions contains two Push VLAN actions, two VLAN headers are added to the packet.

If the list of actions contains an output action, a clone (copy) of the packet is forwarded in its current state to the desired port where it starts egress processing. If the output action references the ALL reserved port, a clone of the packet start egress processing for each relevant port (see 4.5). If the output action references an non-existent port, the clone of the packet is dropped. If the list of actions contains a group action, a clone of the packet in its current state is processed by the relevant group buckets (see

5.10). The set of pipeline fields is cloned with the packet. Any modifications done to a clone of the packet or its pipeline fields generated by the output or group action, for example changing a header field or the metadata field in a group bucket or an egress table, applies only to that clone and does not apply to the original packet or other clones.

After the execution of the list of actions in an *Apply-Actions* instruction, pipeline execution continues on the modified packet (see 5.1). The action set of the packet is unchanged by the execution of the list of actions.

## 5.8 Actions

A switch is not required to support all action types, just those marked "Required Action" below. The controller can also query the switch about which of the "Optional Action" it supports.

Required Action: Output port\_no. The Output action forwards a packet to a specified OpenFlow port (see 4.1) where it starts egress processing. OpenFlow switches must support forwarding to physical ports, switch-defined logical ports and the required reserved ports (see 4.5).

Required Action: Group group\_id. Process the packet through the specified group (see 5.10). The exact interpretation depends on group type.

Required Action: **Drop**. There is no explicit action to represent drops. Instead, packets whose action sets have no output action and no group action must be dropped. This result could come from empty instruction sets or empty action buckets in the processing pipeline (see 5.6), or after executing a *Clear-Actions* instruction (see 5.5).

Optional Action: **Set-Queue** queue\_id. The set-queue action sets the queue id for a packet. When the packet is forwarded to a port using the output action, the queue id determines which queue attached to this port is used for scheduling and forwarding the packet. Forwarding behavior is dictated by the configuration of the queue and is used to provide basic Quality-of-Service (QoS) support (see section 7.3.5.8).

Optional Action: Meter meter\_id. Direct packet to the specified meter (see 5.11). As the result of the metering, the packet may be dropped (depending on meter configuration and state). If the switch supports meters, it must support this action as the first action in an list of actions, for backward compatibility with earlier versions of the specification. Optionally, a switch supporting meters may also support the meter action in other positions in an list of actions, multiple meter actions in an list of actions and the meter action in the action set (see section 7.3.5.14).

Optional Action: **Push-Tag/Pop-Tag** ethertype. Switches may support the ability to push/pop tags as shown in Table 2. To aid integration with existing networks, we suggest that the ability to push/pop VLAN tags be supported.

Newly pushed tags should *always* be inserted as the outermost tag in the outermost valid location for that tag (see 7.2.6.6). When multiple push actions are added to the action set of the packet, they apply to the packet in the order defined by the action set rules, first MPLS, then PBB, than VLAN (see 5.6). When multiple push actions are included in a list of actions, they apply to the packet in the list order (see 5.7).

Note: Refer to section 5.8.1 for information on default field values.

Action	Associated Data	Description
Push VLAN header	Ethertype	Push a new VLAN header onto the packet.
		The Ethertype is used as the Ethertype for the tag. Only
		Ethertype 0x8100 and 0x88a8 should be used.
Pop VLAN header	-	Pop the outer-most VLAN header from the packet.
Push MPLS header	Ethertype	Push a new MPLS shim header onto the packet.
		The Ethertype is used as the Ethertype for the tag. Only
		Ethertype 0x8847 and 0x8848 should be used.
Pop MPLS header	Ethertype	Pop the outer-most MPLS tag or shim header from the packet.
		The Ethertype is used as the Ethertype for the resulting packet
		(Ethertype for the MPLS payload).
Push PBB header	Ethertype	Push a new PBB service instance header (I-TAG TCI) onto
		the packet (see 7.2.6.6).
		The Ethertype is used as the Ethertype for the tag. Only
		Ethertype 0x88E7 should be used.
Pop PBB header	-	Pop the outer-most PBB service instance header (I-TAG TCI)
		from the packet (see 7.2.6.6).

Table 2: Push/pop tag actions.

Optional Action: Set-Field field\_type value. The various Set-Field actions are identified by their field type and modify the values of respective header fields in the packet (see 7.2.3.7). While not strictly required, the support of rewriting various header fields using Set-Field actions greatly increase the usefulness of an OpenFlow implementation. To aid integration with existing networks, we suggest that VLAN modification actions be supported. Set-Field actions should always be applied to the outermost-possible header (e.g. a "Set VLAN ID" action always sets the ID of the outermost VLAN tag), unless the field type specifies otherwise.

Optional Action: Copy-Field src\_field\_type dst\_field\_type. The Copy-Field action may copy data between any header or pipeline fields. It is typically used to copy data from a header field to a packet register pipeline field or from a packet register pipeline field to a header field, and in some cases from a header field to another header field. A switch may not support all combinations of copies between header or pipeline fields.

Optional Action: Change-TTL ttl. The various Change-TTL actions modify the values of the IPv4 TTL, IPv6 Hop Limit or MPLS TTL in the packet. While not strictly required, the actions shown in Table 3 greatly increase the usefulness of an OpenFlow implementation for implementing routing functions. Change-TTL actions should always be applied to the outermost-possible header.

Action	Associated Data	Description			
Set MPLS TTL	8 bits: New MPLS TTL	Replace the existing MPLS TTL. Only applies to packets			
		with an existing MPLS shim header.			
Decrement MPLS TTL	-	Decrement the MPLS TTL. Only applies to packets with			
		an existing MPLS shim header.			
Set IP TTL 8 bits: New IP TTL Replac		Replace the existing IPv4 TTL or IPv6 Hop Limit and			
		update the IP checksum. Only applies to IPv4 and IPv6			
		packets.			
Table 3 – Continued on next page					

Action	Associated Data	Description
Decrement IP TTL	-	Decrement the IPv4 TTL or IPv6 Hop Limit field and
		update the IP checksum. Only applies to IPv4 and IPv6
		packets.
Copy TTL outwards	-	Copy the TTL from next-to-outermost to outermost
		header with TTL.
		Copy can be IP-to-IP, MPLS-to-MPLS, or IP-to-MPLS.
Copy TTL inwards	-	Copy the TTL from outermost to next-to-outermost
		header with TTL.
		Copy can be IP-to-IP, MPLS-to-MPLS, or MPLS-to-IP.

Table 3 – concluded from previous page

Table 3: Change-TTL actions.

The OpenFlow switch checks for packets with invalid IP TTL or MPLS TTL and rejects them. Checking for invalid TTL does not need to be done for every packet, but it must be done at a minimum every time a *decrement TTL* action is applied to a packet. The asynchronous configuration of the switch may be changed (see 6.1.1) to send packets with invalid TTL to the controllers over the control channel via a packet-in message (see 6.1.2).

## 5.8.1 Default values for fields on push

When a new tag is added via a push action (see 5.8), the push action itself does not specify most of the values for the header fields part of the tag. Most of those are set separately via "set-field" actions. The way those header fields are initialised during the push action depends on if those fields are defined as OpenFlow match fields (see 7.2.3.7) and the state of the packet. Header fields part of tag push operation and defined as OpenFlow match fields are listed in Table 4.

New Fields	Existing $Field(s)$	
VLAN ID	$\leftarrow$	VLAN ID
VLAN priority	$\leftarrow$	VLAN priority
MPLS label	$\leftarrow$	MPLS label
MPLS traffic class	$\leftarrow$	MPLS traffic class
MPLS TTL	$\leftarrow$	$\left\{\begin{array}{l} \text{MPLS TTL} \\ \text{IP TTL} \end{array}\right.$
PBB I-SID	$\leftarrow$	PBB I-SID
PBB I-PCP	$\leftarrow$	VLAN PCP
PBB C-DA	$\leftarrow$	ETH DST
PBB C-SA	$\leftarrow$	ETH SRC

Table 4: Existing fields that may be copied into new fields on a push action.

When executing a push action, for all fields specified in Table 4 part of the added header, the value from the corresponding field in the existing outer headers of the packet should be copied in the new field. If the corresponding outer header field does not exist in the packet, the new field should be set to zero.

Header fields which are not defined as OpenFlow match fields should be initialized to appropriate protocol values: those header fields should be set in compliance with the specification governing that field, taking into account the packet headers and the switch configuration. For example, the DEI bit in the VLAN header should be set to zero in most cases.

Fields in new headers may be overridden by specifying a "set-field" action for the appropriate field(s) after the push operation. The execution order of actions in the action set is designed to facilitate that process (see 5.6).

## 5.9 Counters

Counters are maintained for each flow table, flow entry, port, queue, group, group bucket, meter and meter band. OpenFlow-compliant counters may be implemented in software and maintained by polling hardware counters with more limited ranges. Table 5 contains the set of counters defined by the OpenFlow specification. A switch is not required to support all counters, just those marked "Required" in Table 5.

Duration refers to the amount of time the flow entry, a port, a group, a queue or a meter has been installed in the switch, and must be tracked with second precision. The Receive Errors field is the total of all receive and collision errors defined in Table 5, as well as any others not called out in the table.

Packet related counters for an OpenFlow object must count every packet using that object, even if the object is having no effect on the packet or if the packet is ultimately dropped or sent to the controller. For example, the switch should maintain the packet related counters of the following:

- a flow entry with only a goto-table instruction and without actions
- a group outputing to a non-existent port
- a flow entry triggering a TTL exception
- a port which is down

Counters are unsigned and wrap around with no overflow indicator. If a specific numeric counter is not available in the switch, its value must be set to the maximum field value (the unsigned equivalent of -1).

## 5.10 Group Table

A group table consists of group entries. The ability for a flow entry to point to a *group* enables OpenFlow to represent additional methods of forwarding (e.g. select and all).

Each group entry (see Table 6) is identified by its group identifier and contains:

- group identifier: a 32 bit unsigned integer uniquely identifying the group on the OpenFlow switch.
- group type: to determine group semantics (see Section 5.10.1).
- **counters**: updated when packets are processed by a group.

Per Flow Table	Counter	Bits	
Packet Lookups         64         Optional           Packet Matches         64         Optional           Per Flow Entry         Received Packets         64         Optional           Received Bytes         64         Optional           Duration (seconds)         32         Required           Duration (nanoseconds)         32         Optional           Received Packets         64         Required           Transmitted Packets         64         Required           Receive Bytes         64         Optional           Receive Drops         64         Optional           Receive Drops         64         Optional           Receive Errors         64         Optional           Receive Errors         64         Optional           Receive Frame Alignment Errors         64         Optional           Receive CRC Errors         64         Optional           Collisions         64         Optional           Duration	Per Flow Table		
Packet Matches         64         Optional           Received Packets         64         Optional           Received Bytes         64         Optional           Duration (seconds)         32         Required           Duration (nanoseconds)         32         Optional           Per Port           Received Packets         64         Required           Transmitted Packets         64         Required           Received Bytes         64         Optional           Receive Bytes         64         Optional           Receive Drops         64         Optional           Receive Drops         64         Optional           Receive Errors         64         Optional           Receive Errors         64         Optional           Receive Frame Alignment Errors         64         Optional           Receive Overrun Errors         64         Optional           Receive CRC Errors         64         Optional           Receive CRC Errors         64         Optional           Duration (seconds)         32         Required           Duration (seconds)         32         Optional           Transmit Packets         64         Required <td>Reference Count (active entries)</td> <td>32</td> <td>Required</td>	Reference Count (active entries)	32	Required

Table 5: List of counters.

Table 6: Main components of a group entry in the group table.

• action buckets: an ordered list of action buckets, where each action bucket contains a set of actions to execute and associated parameters. The actions in a bucket are always applied as an action set (see 5.6).

## 5.10.1 Group Types

A switch is not required to support all group types, just those marked "Required" below. The controller can also query the switch about which of the "Optional" group types it supports.

- Required: indirect: Execute the one defined bucket in this group. This group supports only a single bucket. Allows multiple flow entries or groups to point to a common group identifier, supporting faster, more efficient convergence (e.g. next hops for IP forwarding). This group type is effectively identical to an all group with one bucket. This group is the simplest type of group, and therefore switches will typically support a greater number of them than other group types.
- Required: all: Execute all buckets in the group. This group is used for multicast or broadcast forwarding. The packet is effectively cloned for each bucket; one packet is processed for each bucket of the group. If a bucket directs a packet explicitly out the ingress port, this packet clone is dropped. If the controller writer wants to forward out the ingress port, the group must include an extra bucket which includes an output action to the OFPP\_IN\_PORT reserved port.
- Optional: select: Execute one bucket in the group. Packets are processed by a single bucket in the group, based on a switch-computed selection algorithm (e.g. hash on some user-configured tuple or simple round robin). All configuration and state for the selection algorithm is external to OpenFlow. The selection algorithm should implement equal load sharing and can optionally be based on bucket weights. When a port specified in a bucket in a select group goes down, the switch may restrict bucket selection to the remaining set (those with forwarding actions to live ports) instead of dropping packets destined to that port. This behavior may reduce the disruption of a downed link or switch.
- Optional: fast failover: Execute the first live bucket. Each action bucket is associated with a specific port and/or group that controls its liveness. The buckets are evaluated in the order defined by the group, and the first bucket which is associated with a live port/group is selected. This group type enables the switch to change forwarding without requiring a round trip to the controller. If no buckets are live, packets are dropped. This group type must implement a liveness mechanism (see 6.7).

#### 5.11 Meter Table

A meter table consists of meter entries, defining per-flow meters. Per-flow meters enable OpenFlow to implement various simple QoS operations, such as rate-limiting, and can be combined with per-port queues (see 5.8) to implement complex QoS frameworks, such as DiffServ.

A meter measures the rate of packets assigned to it and enables controlling the rate of those packets. Meters are attached directly to flow entries (as opposed to queues which are attached to ports). Any flow entry can specify a meter in a list of actions (see 5.8): the meter measures and controls the rate of the aggregate of all flow entries to which it is attached. Multiple meters can be used in the same table, either in an exclusive way (disjoint set of flow entries), or using multiple meter action per flow entry if the switch supports it. Multiple meters can be used on the same set of packets, either by using them in successive flow tables, or using multiple meter action per flow entry if the switch supports it.

Meter Identifier   Meter Bands   Counters
---

Table 7: Main components of a meter entry in the meter table.

Each meter entry (see Table 7) is identified by its meter identifier and contains:

- meter identifier: a 32 bit unsigned integer uniquely identifying the meter
- meter bands: an unordered list of meter bands, where each meter band specifies the rate of the band and the way to process the packet
- counters: updated when packets are processed by a meter

#### 5.11.1 Meter Bands

Each meter may have one or more meter bands. Each band specifies the rate at which the band applies and the way packets should be processed. Packets are processed by a single meter band based on the current measured meter rate. The meter applies the meter band with the highest configured rate that is lower than the current measured rate. If the current rate is lower than any specified meter band rate, no meter band is applied.

Band Type	Rate	Burst	Counters	Type specific arguments

Table 8: Main components of a meter band in a meter entry.

Each meter band (see Table 8) is identified by its rate and contains:

- band type: defines how packet are processed
- rate: used by the meter to select the meter band, defines the lowest rate at which the band can apply
- burst: defines the granularity of the meter band
- counters: updated when packets are processed by a meter band
- type specific arguments: some band types have optional arguments

There is no band type "Required" by this specification. The controller can query the switch about which of the "Optional" meter band types it supports.

• Optional: drop: drop (discard) the packet. Can be used to define a rate limiter band.

• Optional: dscp remark: increase the drop precedence of the DSCP field in the IP header of the packet. Can be used to define a simple DiffServ policer.

## 5.12 Ingress and egress processing differences

Flow tables can be used for ingress or egress processing (see 5.1). Ingress processing is the main processing that happens when the packet enters the OpenFlow switch, and may involve one or more flow tables. Egress processing is the processing that happens after the determination of the output port, it happens in the context of the output port and may involve zero or more flow tables.

There are few differences between flow table used for ingress and egress processing, the flow entries have the same components (see 5.2), flow table matching is the same (see 5.3) and execution of instructions is the same (see 5.5). Table miss processing is the same (see 5.4), and therefore the controller is strongly advised to set a table-miss flow entry in each egress table to avoid dropped packets. In some cases, a flow table can be reconfigured for ingress or egress processing by changing the first egress table (see 7.3.2).

At the beginning of ingress processing, the action set is empty. Flow tables used for ingress processing can only direct packets via the *Goto-Table* instruction to ingress flow tables, and can not direct packets to egress flow tables using the *Goto-Table* instruction. Ingress flow tables usually don't support the *Action Set Output* match field, but may support it in some cases.

At the beginning of egress processing, the action set contains only an *output* action for the current output port. Valid values for that output action are any physical or logical port, or the *CONTROLLER* or *LOCAL* reserved ports (see 4.5), other reserved ports must be substituted with their actual value. The values of the pipeline fields are preserved, except for the *Action Set Output* match field; for example the initial value of the Metadata match field is the value it had when the packet was sent to egress processing. Flow tables used for egress processing can only direct packets via the *Goto-Table* instruction to egress flow tables. They must support the *Action Set Output* match field, to allow flows to be based on the output port context. They must forbid the use of an *output* action or *group* action in *write-action* instruction, so that the packet output port can not be changed. Those restrictions must be advertised in the flow table features (see 7.3.5.18).

The egress tables may optionally support the *output* action or *group* action in *apply-action* instruction. Those actions behave like they do in an ingress table, they forward clones of the packet to the specified ports, those clones must start egress processing from the first egress table (see 5.7). If supported, this can be used for example for selective egress mirroring. A switch should protect itself from packet infinite loops when using *output* action or *group* action in egress tables, this mechanism is implementation specific and outside the scope of this specification.

## 6 OpenFlow Channel and Control Channel

The OpenFlow channel is the interface that connects each OpenFlow Logical Switch to an OpenFlow controller. Through this interface, the controller configures and manages the switch, receives events from the switch, and sends packets out the switch. The Control Channel of the switch may support a single OpenFlow channel with a single controller, or multiple OpenFlow channels enabling multiple controllers to share management of the switch.

Between the datapath and the OpenFlow channel, the interface is implementation-specific, however all OpenFlow channel messages must be formatted according to the OpenFlow switch protocol. The OpenFlow channel is usually encrypted using TLS, but may be run directly over TCP.

## 6.1 OpenFlow Switch Protocol Overview

The OpenFlow switch protocol supports three message types, controller-to-switch, asynchronous, and symmetric, each with multiple sub-types. Controller-to-switch messages are initiated by the controller and used to directly manage or inspect the state of the switch. Asynchronous messages are initiated by the switch and used to update the controller of network events and changes to the switch state. Symmetric messages are initiated by either the switch or the controller and sent without solicitation. The message types used by OpenFlow are described below.

## 6.1.1 Controller-to-Switch

Controller/switch messages are initiated by the controller and may or may not require a response from the switch.

**Features**: The controller may request the identity and the basic capabilities of a switch by sending a features request; the switch must respond with a features reply that specifies the identity and basic capabilities of the switch. This is commonly performed upon establishment of the OpenFlow channel.

**Configuration**: The controller is able to set and query configuration parameters in the switch. The switch only responds to a query from the controller.

Modify-State: Modify-State messages are sent by the controller to manage state on the switches. Their primary purpose is to add, delete and modify flow/group entries and insert/remove action buckets of group in the OpenFlow tables and to set switch port properties.

**Read-State**: Read-State messages are used by the controller to collect various information from the switch, such as current configuration, statistics and capabilities. Most Read-State requests and replies are implemented using multipart message sequences (see 7.3.5).

**Packet-out**: These are used by the controller to send packets out of a specified port on the switch, and to forward packets received via Packet-in messages. Packet-out messages must contain a full packet or a buffer ID referencing a packet stored in the switch. The message must also contain a list of actions to be applied in the order they are specified; an empty list of actions drops the packet.

**Barrier**: Barrier request/reply messages are used by the controller to ensure message dependencies have been met or to receive notifications for completed operations.

**Role-Request**: Role-Request messages are used by the controller to set the role of its OpenFlow channel, set its Controller ID, or query these. This is mostly useful when the switch connects to multiple controllers (see 6.3.6).

**Asynchronous-Configuration**: The Asynchronous-Configuration messages are used by the controller to set an additional filter on the asynchronous messages that it wants to receive on its OpenFlow channel, or to query that filter. This is mostly useful when the switch connects to multiple controllers (see 6.3.6) and commonly performed upon establishment of the OpenFlow channel.

#### 6.1.2 Asynchronous

Asynchronous messages are sent without a controller soliciting them from a switch. Switches send asynchronous messages to controllers to denote a packet arrival or switch state change. The main asynchronous message types are described below.

**Packet-in:** Transfer the control of a packet to the controller. For all packets forwarded to the **CONTROLLER** reserved port using a flow entry or the table-miss flow entry, a packet-in event is always sent to controllers (see 5.8). Other processing, such as TTL checking, may also generate packet-in events to send packets to the controller.

Packet-in events can be configured to buffer packets. For packet-in generated by an output action in a flow entries or group bucket, it can be specified individually in the output action itself (see 7.2.6.1), for other packet-in it can be configured in the switch configuration (see 7.3.2). If the packet-in event is configured to buffer packets and the switch has sufficient memory to buffer them, the packet-in event contain only some fraction of the packet header and a buffer ID to be used by a controller when it is ready for the switch to forward the packet. Switches that do not support internal buffering, are configured to not buffer packets for the packet-in event, or have run out of internal buffering, must send the full packet to controllers as part of the event. Buffered packets will usually be processed via a **Packet-out** or **Flow-mod** message from a controller, or automatically expired after some time.

If the packet is buffered, the number of bytes of the original packet to include in the packet-in can be configured. By default, it is 128 bytes. For packet-in generated by an output action in a flow entries or group bucket, it can be specified individually in the output action itself (see 7.2.6.1), for other packet-in it can be configured in the switch configuration (see 7.3.2).

**Flow-Removed:** Inform the controller about the removal of a flow entry from a flow table. Flow-Removed messages are only sent for flow entries with the OFPFF\_SEND\_FLOW\_REM flag set. They are generated as the result of a controller flow delete request or the switch flow expiry process when one of the flow timeouts is exceeded (see 6.5).

**Port-status:** Inform the controller of a change on a port. The switch is expected to send port-status messages to controllers as port configuration or port state changes. These events include change in port configuration events, for example if it was brought down directly by a user, and port state change events, for example if the link went down.

Role-status: Inform the controller of a change of its role. When a new controller elects itself master, the switch is expected to send role-status messages to the former master controller (see 6.3.6).

Controller-Status: Inform the controller when the status of an OpenFlow channel changes. The switch sends these messages to all controllers when the status of the OpenFlow channel to any switch changes. This can assist failover processing if controllers lose the ability to communicate among themselves.

**Flow-monitor:** Inform the controller of a change in a flow table. A controller may define a set of monitors to track changes in flow tables (see 7.3.5.19).

#### 6.1.3 Symmetric

Symmetric messages are sent without solicitation, in either direction.

Hello: Hello messages are exchanged between the switch and controller upon connection startup.

Echo: Echo request/reply messages can be sent from either the switch or the controller, and must return an echo reply. They are mainly used to verify the liveness of a controller-switch connection, and may as well be used to measure its latency or bandwidth.

Error: Error messages are used by the switch or the controller to notify problems to the other side of the connection. They are mostly used by the switch to indicate a failure of a request initiated by the controller.

**Experimenter:** Experimenter messages provide a standard way for OpenFlow switches to offer additional functionality within the OpenFlow message type space. This is a staging area for features meant for future OpenFlow revisions.

# 6.2 Message Handling

The OpenFlow switch protocol provides reliable message delivery and processing, but does not automatically provide acknowledgements or ensure ordered message processing. The OpenFlow message handling behaviour described in this section is provided on the main connection and auxiliary connections using reliable transport, however it is not supported on auxiliary connections using unreliable transport (see 6.3.7).

Message Delivery: Messages are guaranteed delivery, unless the OpenFlow channel fails entirely, in which case the controller should not assume anything about the switch state (e.g., the switch may have gone into "fail standalone mode").

Message Processing: Switches must process every message received from a controller in full, possibly generating a reply. If a switch cannot completely process a message received from a controller, it must send back an error message. For packet-out messages, fully processing the message does not guarantee that the included packet actually exits the switch. The included packet may be silently dropped after OpenFlow processing due to congestion at the switch, QoS policy, or if sent to a blocked or invalid port.

In addition, switches must send to the controller all asynchronous messages generated by OpenFlow state changes, such as flow-removed, port-status or packet-in messages, so that the controller view of the switch is consistent with its actual state. Those messages may get filtered out based on the Asynchronous Configuration (see 6.1.1). Moreover, conditions that would trigger an OpenFlow state change may get filtered prior to causing such change. For example, packets received on data ports that should be forwarded to the controller may get dropped due to congestion or QoS policy within the switch and generate no packet-in messages. These drops may occur for packets with an explicit output action to the controller. These drops may also occur when a packet fails to match any entries in a table and that table's default action is to send to the controller. The policing of packets destined to the controller is advised, to prevent denial of service of the controller connection, this can be done via a queue on the controller port (see 7.3.5.8) or using per-flow meters (see 5.11).

38

Controllers are free to ignore messages they receive, but must respond to echo messages to prevent the switch from terminating the connection.

Message Grouping: The controller can group together related messages using the optional *Bundle* messages (see 6.9). The set of messages in the bundle are applied as a unit, they are processed together, and if any errors arise, none of the messages is applied. If the bundle is configured as ordered, the set of messages in the bundle is also applied in order. The processing of a bundle is independent of the processing of other messages and other bundles.

Message Ordering: Ordering of messages can be ensured through the use of barrier messages (see 7.3.7). In the absence of barrier messages, switches may arbitrarily reorder messages to maximize performance; hence, controllers should not depend on a specific processing order. In particular, flow entries may be inserted in tables in an order different than that of flow mod messages received by the switch. Messages must not be reordered across a barrier message and the barrier message must be processed only when all prior messages have been processed. More precisely:

- 1. messages before a barrier must be fully processed before the barrier, including sending any resulting replies or errors
- 2. the barrier must then be processed, state is committed to the datapath and a barrier reply sent
- 3. messages after the barrier may then begin processing

If two messages from the controller depend on each other, they must either be separated by a barrier message or be put in the same ordered bundle. Examples of such message dependencies include a group mod add with a flow mod add referencing the group, a port mod with a packet-out forwarding to the port, or a flow mod add with a following packet-out to OFPP\_TABLE.

# 6.3 OpenFlow Channel Connections

The OpenFlow channel is used to exchange OpenFlow message between an OpenFlow switch and an OpenFlow controller. A typical OpenFlow controller manages multiple OpenFlow channels, each one to a different OpenFlow switch. An OpenFlow switch may have one OpenFlow channel to a single controller, or multiple channels for reliability, each to a different controller (see 6.3.6).

An OpenFlow controller typically manages an OpenFlow switch remotely over one or more networks. The specification of the networks used for the OpenFlow channels is outside the scope of the present specification. It may be a separate dedicated network (out-of-band controller connection), or the OpenFlow channel may use the network managed by the OpenFlow switch (in-band controller connection). The only requirement is that it should provide TCP/IP connectivity.

The OpenFlow channel is usually instantiated as a single network connection between the switch and the controller, using TLS or plain TCP (see 6.3.5). Alternatively, the OpenFlow channel may be composed of multiple network connections to exploit parallelism (see 6.3.7). The OpenFlow switch must be able to create an OpenFlow channel by initiating a connection to an OpenFlow controller (see 6.3.2). Some switch implementations may optionally allow an OpenFlow controller to connect to the OpenFlow switch, in this case the switch usually should restrict itself to secured connections (see 6.3.5) to prevent unauthorised connections.

#### 6.3.1 Connection URI

The switch identifies a controller connection by a unique **Connection URI**. This URI must conform to the syntax for URI defined in RFC 3986, in particular with respect to character encoding. The Connection URI may have one of the following form:

- protocol:name-or-address:port
- protocol:name-or-address

The *protocol* field defines the transport used for OpenFlow messages. Acceptable values for *protocol* are tls or tcp for main connections. Acceptable values for auxiliary connections (see 6.3.7) are tls, dtls, tcp, or udp.

The name-or-address field is the hostname or IP address of the controller. If the hostname is locally configured, it is recommended that the URI uses the IP address. If the hostname is available via DNS the URI may use either, so long as it is consistent. When the address is IPv6, the address should be enclosed in square brackets, as recommended in RFC 2732.

The *port* field is the transport port used on the controller. If the *port* field is not specified, it must be equivalent to setting this field to the default OpenFlow transport port 6653.

If the switch implementation supports a transport for the OpenFlow connection that is not defined by this specification, it must use a *protocol* that properly identifies that transport type. In this case, the rest of the Connection URI is protocol defined.

Some examples of Connection URIs are given below.

• tcp:198.168.10.98:6653

• tcp:198.168.10.98

• tls:test.opennetworking.org:6653

• tls:[3ffe:2a00:100:7031::1]:6653

The Connection URI always represents the switch's view of the connection information. If the address or port is translated by the network, this may not match the controller's view of the address or port. Controllers can request a unique ID not subject to network translation (see 6.3.6).

#### 6.3.2 Connection Setup

The switch must be able to establish communication with a controller at a user-configurable (but otherwise fixed) Connection URI, using either a user-specified transport port or the default OpenFlow transport port 6653. If the switch is configured with the Connection URI of the controller to connect to, the switch initiates a standard TLS or TCP connection to the controller as specified by the fields of the Connection URI. The switch must enable such connections to be established and maintained. For out-of-band connections, the switch must make sure that traffic to and from the OpenFlow channel is not run through the OpenFlow pipeline. For in-band connections, the switch must set up the proper set of flow entries for the connection in the OpenFlow pipeline.

Optionally, the switch may allow the controller to initiate the connection. In this case, the switch should accept incomming standard TLS or TCP connections from the controller, using either a user-specified transport port or the default OpenFlow transport port 6653. Connections initiated by the switch and the controller behave the same once the transport connection is established.

When an OpenFlow connection is first established, each side of the connection must immediately send an OFPT\_HELLO message with the version field set to the highest OpenFlow switch protocol version supported by the sender (see 7.1.1). This Hello message may optionally include some OpenFlow elements to help connection setup (see 7.5.1). Upon receipt of this message, the recipient must calculate the OpenFlow switch protocol version to be used. If both the Hello message sent and the Hello message received contained a OFPHET\_VERSIONBITMAP hello element, and if those bitmaps have some common bits set, the negotiated version must be the highest version set in both bitmaps. Otherwise, the negotiated version must be the smaller of the version number that was sent and the one that was received in the version fields.

If the negotiated version is supported by the recipient, then the connection proceeds. Otherwise, the recipient must reply with a *Hello Failed* error message (see 7.5.4.1), and then terminate the connection.

After the switch and the controller have exchanged OFPT\_HELLO messages and successfully negotiated a common version number, the connection setup is done and standard OpenFlow messages can be exchanged over the connection. One of the first thing that the controller should do is to send a OFPT\_FEATURES\_REQUEST message to get the *Datapath ID* of the switch (see 7.3.1).

#### 6.3.3 Connection Maintenance

OpenFlow connection maintenance is mostly done by the underlying TLS or TCP connection mechanisms, this insures that OpenFlow connections are supported on a wide range of networks and conditions. The main mechanisms to detect connection interruption and terminate the connection must be TCP timeouts and TLS session timeouts (when available).

Each connection must be maintained separately, if the connection with a specific controller or switch is terminated or broken, this should not cause connections to other controllers or switches to be terminated (see 6.3.6). Auxiliary connections must be terminated when the corresponding main connection is terminated or broken (see 6.3.7), on the other hand if an auxiliary connection is terminated or broken this should not impact the main connection or other auxiliary connections.

When a connection is terminated due to network conditions or timeout, if a switch or controller was the originator of the connection, it should attempt to reconnect to the other party until a new connection is established or until the Connection URI of the other party is removed from its configuration. Reconnection attempts, when done, should be done at increasing intervals to avoid overwhelming both the network and the other party, the initial interval should be greater than the underlying full TCP connection setup timeout.

OpenFlow messages are processed out of order (see 6.2), and the processing of some requests by the switch may take a long time, a controller must never terminate a connection because a request is taking too much time. An exception to that rule is for *echo replies*, a controller or a switch may terminate a connection if the reply for an echo request it sent takes too much time, however there must be a way to disable that feature and the timeout should be large enough to accommodate a wide variety of conditions.

A controller or switch may terminate the connection when receiving an OpenFlow error message, for example if no common OpenFlow version can be found (see 6.3.2), or if an essential feature is not supported by the other party. In this case, the party that terminated the connection should not attempt to automatically reconnect.

Flow control is also done using the underlying TCP mechanisms (when available). For connections based on TCP, if the switch or controller can not process incoming OpenFlow messages fast enough, it should stop servicing that connection (stop reading messages from the socket) to induce TCP flow control to stop the sender. Controllers should monitor their sending queue and avoid it getting too large. For auxiliary connections based on UDP, if the switch or controller can not process incoming OpenFlow messages fast enough, it should drop excess messages.

#### 6.3.4 Connection Interruption

In the case that a switch loses contact with a controller, it must send a Controller Status message to all remaining connected controllers (if any) indicating the role and control channel status of the affected controller. If the switch loses contact with multiple controllers, it must send multiple Controller Status messages, one for each affected controller. This allows remaining controllers to take action even if they have also lost communication with one another. When the OpenFlow channel is reestablished, the switch must send an updated Controller-Status message to all controllers.

In the case that a switch loses contact with all controllers, as a result of echo request timeouts, TLS session timeouts, or other disconnections, the switch must *immediately* enter either "fail secure mode" or "fail standalone mode", depending upon the switch implementation and configuration. In "fail secure mode", the only change to switch behavior is that packets and messages destined to the controllers are dropped. Flow entries should continue to expire according to their timeouts in "fail secure mode". In "fail standalone mode", the switch processes all packets using the OFPP\_NORMAL reserved port; in other words, the switch acts as a legacy Ethernet switch or router. When in "fail standalone mode", the switch is free to use flow tables in any way it wishes, the switch may delete, add or modify any flow entry. The "fail standalone mode" is usually only available on Hybrid switches (see 5.1).

When the OpenFlow channel is reestablished, the flow entries present in the flow tables at that time are preserved and normal OpenFlow operation resumes. If desired, the controller has then the option of reading all flow entries with a *flow-stats* request (see 7.3.5.2), to re-synchronise its state with the switch state. Alternatively, the controller then has the option of deleting all flow entries with a *flow-mod* request (see 6.4), to start from a clean state on the switch.

The first time a switch starts up, it will operate in either "fail secure mode" or "fail standalone mode" mode, until it is successfully connected to a controller. Configuration of the default set of flow entries to be used at startup is outside the scope of the OpenFlow switch protocol.

# 6.3.5 Encryption

The switch and controller may communicate through a TLS connection. If a valid Connection URI specifies tls as the protocol, a TLS connection is initiated by the switch on startup to the controller, which is listening either on a user-specified TCP port or on the default TCP port 6653. Optionally, the TLS connection is initiated by the controller to the switch, which is listening either on a user-specified

TCP port or on the default TCP port 6653. The switch and controller mutually authenticate by exchanging certificates signed by a site-specific private key. Each switch must be user-configurable with one certificate for authenticating the controller (controller certificate) and the other for authenticating to the controller (switch certificate).

The switch and controller may optionally communicate using plain TCP. Plain TCP can be used for non-encrypted communication (not recommended), or to implement an alternate encryption configuration, such as using IPsec or VPN, the detail of such configuration is outside the specification. If a valid Connection URI specifies tcp as the protocol, the TCP connection is initiated by the switch on startup to the controller, which is listening either on a user-specified TCP port or on the default TCP port 6653. Optionally, the TCP connection is initiated by the controller to the switch, which is listening either on a user-specified TCP port or on the default TCP port 6653. When using plain TCP, it is recommended to use alternative security measures to prevent eavesdropping, controller impersonation or other attacks on the OpenFlow channel.

#### 6.3.6 Multiple Controllers

The switch may establish communication with a single controller, or may establish communication with multiple controllers. Having multiple controllers improves reliability, as the switch can continue to operate in OpenFlow mode if one controller or controller connection fails. The hand-over between controllers is initiated by the controllers themselves, which enables fast recovery from failure and also controller load balancing. The controllers coordinate the management of the switch amongst themselves via mechanisms outside the scope of the present specification, and the goal of the multiple controller functionality is only to help synchronise controller handoffs performed by the controllers. The multiple controller functionality only addresses controller fail-over and load balancing, and doesn't address virtualisation which can be done outside the OpenFlow switch protocol.

When OpenFlow operation is initiated, the switch must connect to all controllers it is configured with, and try to maintain connectivity with all of them concurrently. Many controllers may send controller-to-switch commands to the switch, the reply or error messages related to those commands must only be sent on the controller connection associated with that command. Asynchronous messages may need to be sent to multiple controllers, the message is duplicated for each eligible OpenFlow channel and each message sent when the respective controller connection allows it.

The default role of a controller is OFPCR\_ROLE\_EQUAL. In this role, the controller has full access to the switch and is equal to other controllers in the same role. By default, the controller receives all the switch asynchronous messages (such as packet-in, flow-removed). The controller can send controller-to-switch commands to modify the state of the switch. The switch does not do any arbitration or resource sharing between controllers.

A controller can request its role to be changed to OFPCR\_ROLE\_SLAVE. In this role, the controller has read-only access to the switch. By default, the controller does not receive switch asynchronous messages, apart from Port-status messages. The controller is denied the ability to execute all controller-to-switch commands that send packets or modify the state of the switch. For example, OFPT\_PACKET\_OUT, OFPT\_FLOW\_MOD, OFPT\_GROUP\_MOD, OFPT\_PORT\_MOD, OFPT\_TABLE\_MOD requests, and OFPMP\_TABLE\_FEATURES multiparts requests with a non-empty body must be rejected. If the controller sends one of those commands, the switch must reply with an *Is Slave* error message (see

7.5.4.2). Other controller-to-switch messages, such as OFPT\_ROLE\_REQUEST, OFPT\_SET\_ASYNC and OFPT\_MULTIPART\_REQUEST that only query data, should be processed normally.

A controller can request its role to be changed to OFPCR\_ROLE\_MASTER. This role is similar to OFPCR\_ROLE\_EQUAL and has full access to the switch, the difference is that the switch ensures it is the only controller in this role. When a controller changes its role to OFPCR\_ROLE\_MASTER, the switch changes the current controller with the role OFPCR\_ROLE\_MASTER to have the role OFPCR\_ROLE\_SLAVE, but does not affect controllers with role OFPCR\_ROLE\_EQUAL. When the switch performs such role changes, if a controller role is changed from OFPCR\_ROLE\_MASTER to OFPCR\_ROLE\_SLAVE, the switch must generate a controller role status event for this controller informing it of its new state (in many cases that controller is no longer reachable, and switch may not be able to transmit that event).

Each controller may send a OFPT\_ROLE\_REQUEST message to communicate its role to the switch (see 7.3.8), and the switch must remember the role of each controller connection. A controller may change role at any time, provided the generation\_id in the message is current (see below).

The role request message offers a lightweight mechanism to help the controller master election process, the controllers configure their role and usually still need to coordinate among themselve. The switch can not change the state of a controller on its own, controller state is always changed as a result of a request from one of the controllers. Any Slave controller or Equal controller can elect itself Master. A switch may be *simultaneously* connected to multiple controllers in Equal state, multiple controllers in Slave state, and at most one controller in Master state. The controller in Master state (if any) and all the controllers in Equal state can fully change the switch state, there is no mechanism to enforce partitioning of the switch between those controllers. If the controller in Master role need to be the only controller able to make changes on the switch, then no controllers should be in Equal state and all other controllers should be in Slave state.

Controllers may also use the OFPT\_ROLE\_REQUEST message to set the ID number the switch uses in Controller-Status messages. This is particularly useful when the OpenFlow connection traverses a NAT boundary that changes IP identifiers, since the URI in the Controller-Status message always represents the switch's view of the connection (see 6.3.1).

A controller can also control which types of switch asynchronous messages are sent over its OpenFlow channel, and change the defaults described above. This is done via a *Asynchronous Configuration* message (see 6.1.1), listing all reasons for each message type that need to be enabled or filtered out (see 7.3.10) for the specific OpenFlow channel. Using this feature, different controllers can receive different notifications, a controller in master mode can selectively disable notifications it does not care about, and a controller in slave mode can enable notifications it wants to monitor.

To detect out-of-order messages during a master/slave transition, the OFPT\_ROLE\_REQUEST message contains a 64-bit sequence number field, generation\_id, that identifies a given mastership view. As a part of the master election mechanism, controllers (or a third party on their behalf) coordinate the assignment of generation\_id. generation\_id is a monotonically increasing counter: a new (larger) generation\_id is assigned each time the mastership view changes, e.g. when a new master is designated. generation\_id can wrap around.

On receiving a OFPT\_ROLE\_REQUEST with role equal to OFPCR\_ROLE\_MASTER or OFPCR\_ROLE\_SLAVE the switch must compare the generation\_id in the message against the largest generation id seen so far. A message with a generation\_id smaller than a previously seen generation id must be considered stale and discarded, and the switch must reply with a *Stale* error message (see 7.5.4.12).

The following pseudo-code describes the behavior of the switch in dealing with generation\_id.

## On switch startup:

```
generation_is_defined = false;
```

On receiving OFPT\_ROLE\_REQUEST with role equal to OFPCR\_ROLE\_MASTER or OFPCR\_ROLE\_SLAVE and with a given generation\_id, say GEN\_ID\_X:

where distance() is the Wrapping Sequence Number Distance operator defined as following:

```
distance(a, b) := (int64_t)(a - b)
```

I.e. distance() is the unsigned difference between the sequence numbers, interpreted as a two's complement signed value. This results in a positive distance if a is greater than b (in a circular sense) but less than "half the sequence number space" away from it. It results in a negative distance otherwise (a < b).

The switch must ignore generation\_id if the role in the OFPT\_ROLE\_REQUEST is OFPCR\_ROLE\_EQUAL, as generation\_id is specifically intended for the disambiguation of race condition in master/slave transition.

# 6.3.7 Auxiliary Connections

By default, the *OpenFlow channel* between an OpenFlow switch and an OpenFlow controller is a single network connection. The OpenFlow channel may also be composed of a **main connection** and multiple **auxiliary connections**. Auxiliary connections are created by the OpenFlow switch and are helpful to improve the switch processing performance and exploit the parallelism of most switch implementations. Auxiliary connections are always initiated by the switch, but may be configured by the controller.

Each connection from the switch to the controller is identified by the switch *Datapath ID* and a *Auxiliary ID* (see 7.3.1). The main connection must have its Auxiliary ID set to zero, whereas an auxiliary connection must have a non-zero Auxiliary ID and the same Datapath ID. Auxiliary connections must use the same source IP address as the main connection, but can use a different transport, for example TLS, TCP, DTLS or UDP, depending on the switch configuration. The auxiliary connection should have the same destination IP address and same transport destination port as the main connection, unless the switch configuration specifies otherwise. The controller must recognise incoming connections

with non-zero Auxiliary ID as auxiliary connections and bind them to the main connection with the same Datapath ID.

The switch must not initiate auxiliary connection before having completed the connection setup over the main connection (see 6.3.2), it must setup and maintain auxiliary connections with the controller only while the corresponding main connection is alive. The connection setup for auxiliary connections is the same as for the main connection (see 6.3.2). If the switch detects that the main connection to a controller is broken, it must immediately close all its auxiliary connections to that controller, to enable the controller to properly resolve Datapath ID conflicts.

Both the OpenFlow switch and the OpenFlow controller must accept any OpenFlow message types and sub-types on all connections: the main connection or an auxiliary connection can not be restricted to a specific message type or sub-type. However, the processing performance of different message types or sub-types on different connections may be different. The switch may service auxiliary connections with different priorities, for example one auxiliary connection may be dedicated to high priority requests and always processed by the switch before other auxiliary connections. A switch configuration, for example using the OpenFlow Configuration Protocol, may optionally configure the priority of auxiliary connections.

A reply to an OpenFlow request must be made on the same connection it came in. There is no synchronisation between connections, and messages sent on different connections may be processed in any order. A barrier message applies only to the connection where it is used (see 6.2). Auxiliary connections using DTLS or UDP may lose or reorder messages, OpenFlow does not provide ordering or delivery guarantees on those connections (see 6.2). If messages must be processed in sequence, they must be sent over the same connection, use a connection that does not reorder packets, and use barrier messages.

The controller is free to use the various switch connections for sending OpenFlow messages at its entire discretion, however to maximise performance on most switches the following guidelines are suggested:

- All OpenFlow controller requests which are not Packet-out (flow-mod, statistic request...) should be sent over the main connection.
- Connection maintenance messages (hello, echo request, features request) should be sent on the main connection and on each auxiliary connection as needed.
- All Packet-Out messages containing a packet from a Packet-In message should be sent on the connection where the Packet-In came from.
- All other Packet-Out messages should be spread across the various auxiliary connections using a mechanism keeping the packets of a same flow mapped to the same connection.
- If the desired auxiliary connection is not available, the controller should use the main connection.

The switch is free to use the various controller connections for sending OpenFlow messages as it wishes, however the following guidelines are suggested:

- All OpenFlow messages which are not Packet-in should be sent over the main connection.
- All Packet-In messages spread across the various auxiliary connection using a mechanism keeping the packets of a same flow mapped to the same connection.

Auxiliary connections on unreliable transports (UDP, DTLS) have additional restrictions and rules that don't apply to auxiliary connection on other transports (TCP, TLS). The only message types supported on unreliable auxiliary connections are OFPT\_HELLO, OFPT\_ERROR, OFPT\_ECHO\_REQUEST, OFPT\_ECHO\_REPLY, OFPT\_FEATURES\_REQUEST, OFPT\_FEATURES\_REPLY, OFPT\_PACKET\_IN, OFPT\_PACKET\_OUT and OFPT\_EXPERIMENTER, other messages types are not supported by the specification. Each UDP packet must contain an integral number of OpenFlow messages; many OpenFlow messages may be sent in the same UDP packet and OpenFlow message may not be split across UDP packets. Deployments using UDP and DTLS connections are advised to configure the network and switches to avoid IP fragmentation of UDP packets.

On unreliable auxiliary connections, Hello messages are sent at connection initiation to setup the connection (see 6.3.2). If an OpenFlow device receives another message on an unreliable auxiliary connection prior to receiving a Hello message, the device must either assume the connection is setup properly and use the version number from that message, or it must return an Error message with OFPET BAD REQUEST type and OFPBRC BAD VERSION code. If an OpenFlow device receives a error message with OFPET\_BAD\_REQUEST type and OFPBRC\_BAD\_VERSION code on an unreliable auxiliary connection, it must either send a new Hello message or terminate the unreliable auxiliary connection (the connection may be retried at a later time). If no message was ever received on an auxiliary connection after some implementation chosen amount of time lower than 5 seconds, the device must either send a new Hello message or terminate the unreliable auxiliary connection. If after sending a Feature Request message, the controller does not receive a Feature Reply message after some implementation chosen amount of time lower than 5 seconds, the device must either send a new Feature Request message or terminate the unreliable auxiliary connection. If after receiving a message, a device does not receive any other message after some implementation chosen amount of time lower than 30 seconds, the device must terminate the unreliable auxiliary connection. If a device receives a message for an unreliable auxiliary connection already terminated, it must assume it is a new connection.

OpenFlow devices using unreliable auxiliary connections should follow recommendations in RFC 5405 when possible. Unreliable auxiliary connections can be considered as an encapsulation tunnel, as most OpenFlow messages are prohibited apart from OFPT\_PACKET\_IN and OFPT\_PACKET\_OUT messages. If some of the packets encapsulated in the OFPT\_PACKET\_IN messages are not TCP packet or do not belong to a protocol having proper congestion control, the controller should configure the switch to have those messages processed by a Meter or a Queue to manage congestion.

## 6.4 Flow Table Modification Messages

Flow table modification messages can have the following types:

For add requests (OFPFC\_ADD) with the OFPFF\_CHECK\_OVERLAP flag set, the switch must first check for any overlapping flow entries in the requested table. Two flow entries overlap if a single packet may match both, and both entries have the same priority. If an overlap conflict exists between an existing flow entry and the add request, the switch must refuse the addition and respond with an *Overlap* error message (see 7.5.4.6).

For non-overlapping **add** requests, or those with no overlap checking, the switch must insert the flow entry in the requested table. If a flow entry with identical match fields and priority already resides in the requested table, then that entry, including its duration, must be cleared from the table, and the new flow entry added. If the OFPFF\_RESET\_COUNTS flag is set, the flow entry counters must be cleared, otherwise they should be copied from the replaced flow entry. No flow-removed message is generated for the flow entry eliminated as part of an **add** request; if the controller wants a flow-removed message it should explicitly send a **delete** request for the old flow entry prior to adding the new one.

For modify requests (OFPFC\_MODIFY or OFPFC\_MODIFY\_STRICT), if a matching entry exists in the table, the instructions field of this entry is replaced with the value from the request, whereas its cookie, idle\_timeout, hard\_timeout, flags, counters and duration fields are left unchanged. If the OFPFF\_RESET\_COUNTS flag is set, the flow entry counters must be cleared. For modify requests, if no flow entry currently residing in the requested table matches the request, no error is recorded, and no flow table modification occurs.

For **delete** requests (OFPFC\_DELETE or OFPFC\_DELETE\_STRICT), if a matching entry exists in the table, it must be deleted, and if the entry has the OFPFF\_SEND\_FLOW\_REM flag set, it should generate a flow removed message. For **delete** requests, if no flow entry currently residing in the requested table matches the request, no error is recorded, and no flow table modification occurs.

Modify and delete flow\_mod commands have non-strict versions (OFPFC\_MODIFY and OFPFC\_DELETE) and strict versions (OFPFC\_MODIFY\_STRICT or OFPFC\_DELETE\_STRICT). In the strict versions, the set of match fields, all match fields, including their masks, and the priority, are strictly matched against the entry, and only an identical flow entry is modified or removed. For example, if a message to remove entries is sent that has no match fields included, the OFPFC\_DELETE command would delete all flow entries from the tables, while the OFPFC\_DELETE\_STRICT command would only delete a flow entry that applies to all packets at the specified priority.

For non-strict modify and delete commands, all flow entries that match the flow\_mod description are modified or removed. In the non-strict versions, a match will occur when a flow entry exactly matches or is more specific than the description in the flow\_mod command; in the flow\_mod the missing match fields are wildcarded, field masks are active, and other flow\_mod fields such as priority are ignored. For example, if a OFPFC\_DELETE command says to delete all flow entries with a destination port of 80, then a flow entry that wildcards all match fields will not be deleted. However, a OFPFC\_DELETE command that wildcards all match fields will delete an entry that matches all port 80 traffic. This same interpretation of mixed wildcard and exact match fields also applies to individual and aggregate flows stats requests.

Delete commands can be optionally filtered by destination group or output port. If the out\_port field contains a value other than OFPP\_ANY, it introduces a constraint when matching. This constraint is that each matching flow entry must contain an *output* action directed at the specified port in the actions associated with that flow entry. This constraint is limited to only the actions directly associated with the flow entry. In other words, the switch must not recurse through the action buckets of pointed-to groups, which may have matching *output* actions. The out\_group, if different from OFPG\_ANY, introduce

a similar constraint on the *group* action. These fields are ignored by OFPFC\_ADD, OFPFC\_MODIFY and OFPFC\_MODIFY\_STRICT messages.

Modify and delete commands can also be filtered by cookie value, if the cookie\_mask field contains a value other than 0. This constraint is that the bits specified by the cookie\_mask in both the cookie field of the flow mod and a flow entry's cookie value must be equal. In other words,  $(flow\_entry.cookie \& flow\_mod.cookie\_mask) == (flow\_mod.cookie \& flow\_mod.cookie\_mask)$ .

**Delete** commands can use the OFPTT\_ALL value for table-id to indicate that matching flow entries are to be deleted from all flow tables.

If a switch cannot find any space in the requested table in which to add the incoming flow entry, the switch must return a *Table Full* error message (see 7.5.4.6).

The switch must validate the content Flow-mod message and must return the appropriate **error** messages for instruction errors (see 7.5.4.4), match errors (see 7.5.4.5), action errors (see 7.5.4.3), meter errors (see 7.5.4.13) and other flow-mod errors (see 7.5.4.6).

## 6.5 Flow Removal

Flow entries are removed from flow tables in three ways, either at the request of the controller, via the switch flow expiry mechanism, or via the optional switch eviction mechanism.

The switch flow expiry mechanism is run by the switch independently of the controller and is based on the state and configuration of flow entries. Each flow entry has an idle\_timeout and a hard\_timeout associated with it (see 7.3.4.2). If the hard\_timeout field is non-zero, the switch must note the flow entry's arrival time, as it may need to evict the entry later. A non-zero hard\_timeout field causes the flow entry to be removed after the given number of seconds, regardless of how many packets it has matched. If the idle\_timeout field is non-zero, the switch must note the arrival time of the last packet associated with the flow, as it may need to evict the entry later. A non-zero idle\_timeout field causes the flow entry to be removed when it has matched no packets in the given number of seconds. The switch must implement flow expiry and remove flow entries from the flow table when one of their timeouts is exceeded.

The controller may actively remove flow entries from flow tables by sending **delete** flow table modification messages (OFPFC\_DELETE or OFPFC\_DELETE\_STRICT - see 6.4). Flow entries may also be removed as the result of removal of a group (see 6.7) or a meter (see 6.8) by the controller. On the other hand, when a port is added, modified or removed, flow entries are never removed or modified, the controller must explicitly remove those flow entries if needed (see 4.6).

Flow entries may be **evicted** from flow tables when the switch needs to reclaim resources. Flow entry eviction occurs only on flow tables where it is explicitly enabled (see 7.3.3). Flow entry eviction is an optional feature, and the mechanism used to select which flow entries to evict is switch defined and may depend on flow entry parameters, resource mappings in the switch and other internal switch constraints.

When a flow entry is removed, either by the controller, the flow expiry mechanism, or the optional switch eviction mechanism, the switch must check the flow entry's OFPFF\_SEND\_FLOW\_REM flag. If this flag is set, the switch must send a flow removed message to the controller (see 7.4.2). Each flow removed message

contains a complete description of the flow entry, the reason for removal (expiry, delete or eviction), the flow entry duration at the time of removal, and the flow statistics at the time of removal.

# 6.6 Flow Table Synchronisation

A flow table may optionally be *synchronised* with another flow table. When a flow table is synchronised, its content is automatically updated by the switch to reflect changes in the flow table it is synchronised with. This mechanism enables a switch to perform multiple matches on different views of the same data at different points of the OpenFlow pipeline.

Flow tables can be synchronised unidirectionally (one flow table synchronises from another flow table) or bidirectionally (two flow tables synchronise from each other), a switch may also define a flow table that synchronise from multiple tables or that synchronise on itself. The synchronisation of flow tables is described in the table features message, each synchronised flow table includes a table property identifying the source flow tables it synchronises from (see 7.3.5.18). For a synchronised flow table, when a flow entry is added, modified or removed in the source flow table, a corresponding flow entry must be automatically added, modified or removed in the synchronised flow table by the switch. If a flow entry is added in the source flow table with the OFPFF CHECK OVERLAP flag set, and if the corresponding flow entry would overlap a flow entry already residing in the synchronised flow table, the switch must refuse the full flow-mod request and respond with a Can't Sync error message (see 7.5.4.6). If a flow entry is added in the source flow table, and the corresponding flow entry has identical match and priority to a older flow entry already residing in the synchronised flow table, the existing flow entry must be replaced by the synchronised flow entry, no flow removed message is generated for the old flow entry. If a flow entry is modified or removed in the source flow table, and if the corresponding flow entry no longer exists in the synchronised flow table, no flow entry should be modified, removed or created in the synchronised flow table.

The flow entry created in the synchronised table may not be identical to the corresponding flow entry in the source flow table, as they are often different views on the same data. The translation between those synchronised flow entries is not specified by the OpenFlow protocol and depends on the switch implementation and configuration. For example, synchronised flow entries may have a different instruction set and actions, and the match fields may be transposed (source and destination inverted). If the flows tables are synchronised bidirectionally, the translation must be bijective, each translation must be the exact reverse of the other translation, so that a translated flow entry will always translate back to the original source flow entry. The counters of a flow entry must be kept independently of counters in the source flow table, those counters are not synchronised. In general, synchronised flow entries are created as permanent flow entries (both expiry timers set to zero) so that their lifetime is properly synchronised with the flow entries in the source flow table.

The switch may optionally allow the controller to modify or delete those flow entries automatically added in the synchronised table, and may also allow the controller to create new entries in the synchronised table. This enables the controller to customise those synchronised flow entries beyond the switch automatic translation. These changes may be lost if the source flow entry is modified. If flow table synchronisation is bidirectional (both flow table synchronised on each other), changes done by the controller on a flow entry created by the synchronisation mechanism need to be reflected back on the other synchronised flow table (like it would be for a non-synchronised flow entry in that flow table).

The switch may have restrictions on flow table synchronisation. If the switch can't synchronise a flow mod request generated by the controller in the source flow table, the switch must reject the flow mod and immediately return a *Can't Sync* error message (see 7.5.4.6). If the controller attempt to add, modify or delete a flow entry in a synchronised flow table and the switch can't support such changes, the switch must reject the flow mod and immediately return a *Is Sync* error message (see 7.5.4.6).

The flow table synchronisation feature could in theory be used to describe complex synchronisation interactions, such as table synchronising from multiple tables or table synchronising from synchronised tables. This specification recommends to only describe simple and common synchronisation configurations, such as those involving only two tables. In particular, synchronisation loops should be avoided.

A example of the use synchronised tables is to map a Ethernet learning/forwarding hardware table into OpenFlow as a set of two synchronised flow tables. There are multiple ways synchronised flow tables can be used for Ethernet learning/forwarding, this specification makes no recommendations on which way to use. In this illustrative and simplistic example, a first flow table expresses the learning lookup and matches on Ethernet source address and input port (and optionally other fields such as VLAN ID). A second flow table expresses the forwarding lookup and matches on Ethernet destination address and sets the output port. The two tables synchronise from each other, with the Ethernet addresses transposed in the match. Flow entries in the first table are set to expire based on the learning ageing timer, flow entries in the second table are set without expiry timer and are removed automatically when the corresponding flow entry in the first table expires. The controller can add a flow entry in either of those two flow tables, and then modify the instructions of the flow entry automatically added in the other flow table. Another example of using synchronised tables is mapping RPF checks for multicast packets as a flow table.

# 6.7 Group Table Modification Messages

Groups may consist of zero or more buckets. A group with no buckets will not alter the action set associated with a packet. A group may also include buckets which themselves invoke other groups if the switch supports it.

The set of actions for each bucket must be validated using the same rules as those for flow mods (see 7.5.4.3), with additional group-specific checks (see 7.5.4.7).

Group table modification messages can have the following commands:

```
/* Group commands */
enum ofp_group_mod_command {
    OFPGC_ADD
               = 0,
                            /* New group. */
    OFPGC_MODIFY = 1,
                            /* Modify all matching groups. */
    OFPGC_DELETE = 2,
                            /* Delete all matching groups. */
    OFPGC_INSERT_BUCKET = 3,/* Insert action buckets to the already available
                               list of action buckets in a matching group */
    /* OFPGC_??? = 4, */
                            /* Reserved for future use. */
    OFPGC_REMOVE_BUCKET = 5,/* Remove all action buckets or any specific action
                               bucket from matching group */
};
```

A group-mod request with an **add** command (OFPGC\_ADD) adds a new group entry in the group table. If the specified group already exist, the switch must return a *Group Exist* error message (see 7.5.4.7).

For **modify** requests (OFPGC\_MODIFY), if a group entry with the specified group identifier already resides in the group table, then the configuration of that group entry, including its type and action buckets, must be removed (cleared), and the group entry must use the new configuration included in the request. For that entry, group top-level statistics are preserved (continued), group bucket statistics are reset (cleared). If the specified group does not already exist, the switch must must refuse the group mod and send a *Unknown Group* error message (see 7.5.4.7).

For **delete** requests (OFPGC\_DELETE), if no group entry with the specified group identifier currently exists in the group table, no error is recorded, and no group table modification occurs. Otherwise, the group is removed, and all flow entries containing this group in a Group action are also removed. The group type need not be specified for the **delete** request. **Delete** also differs from an **add** or **modify** with no buckets specified in that future attempts to **add** the group identifier will not result in a group exists error. If one wishes to effectively delete a group yet leave in flow entries using it, that group can be cleared by sending a **modify** with no buckets specified.

To delete all groups with a single message, specify OFPG\_ALL as the group value.

For **insert bucket** requests (OFPGC\_INSERT\_BUCKET), if a group entry with the specified group identifier already resides in the group table, new action buckets are inserted at a specified position in the current action bucket list. For that group, group top-level statistics and group bucket statistics for existing buckets are preserved (continued).

The command\_bucket\_id field is used to specify the position in the current action bucket list to insert new action buckets, following are supported command\_bucket\_id field value of OFPGC\_INSERT\_BUCKET request:

- If command\_bucket\_id is OFPG\_BUCKET\_FIRST, the new action buckets will be inserted at the beginning of the list just before the current action buckets, that is, entire current action bucket list will be pushed and appended to the new action buckets. If the current action bucket list is empty, the new actions buckets just replace the current action bucket list.
- If command\_bucket\_id is OFPG\_BUCKET\_LAST, the new action buckets will be inserted after the current bucket list, that is, new action buckets are appended to the current action bucket list. If the current action bucket list is empty, the new actions buckets just replace the current action bucket list.
- If command\_bucket\_id is a valid identifier in the current action bucket list, the new action buckets will be inserted after command\_bucket\_id value, that is, new action buckets will be inserted between bucket identifier value mentioned in command\_bucket\_id and next value of the list. In case the command\_bucket\_id identifies the last bucket, the command\_bucket\_id will be treated as OFPG\_BUCKET\_LAST.

If command\_bucket\_id field value is not one of the reserved values above or does not exist in the current action bucket list, the switch must return a *Unknown Bucket* error message (see 7.5.4.7).

For **remove bucket** requests (OFPGC\_REMOVE\_BUCKET), if a group entry with the specified group identifier already resides in the group table, removes all buckets or the specified bucket from current action bucket list. For that group, group top-level statistics and group bucket statistics for remaining buckets are preserved (continued).

The command\_bucket\_id field is used to specify identifier of the bucket to remove from current action bucket list, following are supported command\_bucket\_id field value of OFPGC\_REMOVE\_BUCKET request:

- If command\_bucket\_id is OFPG\_BUCKET\_ALL, removes all action buckets from the group and thereby the current action bucket list of the group becomes empty.
- If command\_bucket\_id is OFPG\_BUCKET\_FIRST, removes first action bucket from the current action bucket list.
- If command\_bucket\_id is OFPG\_BUCKET\_LAST, removes last action bucket from the current action bucket list.
- If command\_bucket\_id is a valid identifier in the current action bucket list, removes specified action bucket from the list.

Groups may be **chained** if the switch supports it, when at least one group forwards to another group, or in more complex configuration. For example, a fast reroute group may have two buckets, where each points to a select group.

A switch may support checking that no loop is created while chaining groups: if a group mod is sent such that a forwarding loop would be created, the switch must reject the group mod and must send a *Loop* error message (see 7.5.4.7). If the switch does not support such checking, the forwarding behavior is undefined.

A switch may support checking that groups forwarded to by other groups are not removed: If a switch cannot delete a group because it is referenced by another group, it must refuse to delete the group entry and must send a *Chained Group* error message (see 7.5.4.7). If the switch does not support such checking, the forwarding behavior is undefined.

Fast failover group support requires **liveness monitoring**, to determine the specific bucket to execute. Other group types are not required to implement liveness monitoring, but may optionally implement it. If a switch cannot implement liveness checking for any bucket in a group, it must refuse the group mod and return an error. The rules for determining liveness include:

- A port is considered live if it exists in the datapath and has the OFPPS\_LIVE flag set in its port state. Port liveness may be managed by code outside of the OpenFlow portion of a switch, defined outside of the OpenFlow specification, such as Spanning Tree or a KeepAlive mechanism. The port must not be considered live (and the OFPPS\_LIVE flag must be unset) if one of the port liveness mechanisms of the switch enabled on that OpenFlow port considers the port not live, or if the port config bit OFPPC\_PORT\_DOWN indicates the port is down, or if the port state bit OFPPS\_LINK\_DOWN indicates the link is down.
- A bucket is considered live if either watch\_port is not OFPP\_ANY and the port watched is live, or if watch\_group is not OFPG\_ANY and the group watched is live. In other words, the bucket is considered not live if watch\_port is OFPP\_ANY or the port watched is not live, and if watch\_group is OFPG\_ANY or the group watched is not live.
- A group is considered live if a least one of its buckets is live.

The controller can infer the liveness state of the group by monitoring the states of the various ports.

# 6.8 Meter Modification Messages

Meter modification messages can have the following commands:

A meter-mod request with an **add** command (OFPMC\_ADD) adds a new meter entry in the switch. If the specified meter already exist, the switch must return a *Meter Exist* error message (see 7.5.4.13).

For **modify** requests (OFPMC\_MODIFY), if a meter entry with the specified meter identifier already exists, then the configuration of that meter entry, including its flags and bands, must be removed (cleared), and the meter entry must use the new configuration included in the request. For that entry, meter top-level statistics are preserved (continued), meter band statistics are reset (cleared). If a meter entry with the specified meter identifier does not already exist then the switch must refuse the meter mod and send a *Unknown Meter* error message (see 7.5.4.13).

For **delete** requests (OFPMC\_DELETE), if no meter entry with the specified meter identifier currently exists, no error is recorded, and no meter modification occurs. Otherwise, the meter is removed, and all flows that include the meter in their instruction set are also removed. Only the meter identifier need to be specified for the **delete** request, other fields such as **bands** can be omitted.

To delete all meters with a single message, specify OFPM\_ALL as the meter value. Virtual meters can never be deleted and are not removed when deleting all meters.

# 6.9 Bundle Messages

#### 6.9.1 Bundle overview

A bundle is a sequence of OpenFlow modification requests from the controller that is applied as a single OpenFlow operation. If all modifications in the bundle succeed, all of the modifications are retained, but if any errors arise, none of the modifications are retained.

The first goal of bundles is to group related state changes on a switch so that all changes are applied together or that none of them are applied. The second goal is to better synchronise changes across a set of OpenFlow switches: bundles can be prepared and pre-validated on each switch and then applied by the controller approximately at the same time.

A bundle is specified as all messages conveyed in Bundle Add messages with the same bundle\_id on a specific controller connection (see 7.3.9.7). Messages conveyed in a Bundle Add message are formatted like regular OpenFlow messages and have the same semantics. The messages part of a bundle are pre-validated as they are stored in the bundle, minimising the probability of errors when the bundle is applied. The application of the message included in the Bundle Add message is postponed to when the bundle is committed (see 7.3.9.9).

Bundle is an optional feature and may not be supported by all OpenFlow switches. A switch is not required to accept arbitrary messages in a bundle, a switch may not accept some message types in bundles, and a switch may not allow all combinations of message types to be bundled together (see 7.3.9.7). For example, a switch should not allow to embed a bundle message within a Bundle Add message. At a minimum, if a switch supports bundles, it must be able to support a bundle of multiple flow-mods and port-mods in any order.

# 6.9.2 Bundle example usage

The controller can issue the following sequence of messages to apply a sequence of modifications together.

- 1. OFPBCT\_OPEN\_REQUEST bundle\_id
- 2. OFPT\_BUNDLE\_ADD\_MESSAGE bundle\_id modification 1
- 3. OFPT\_BUNDLE\_ADD\_MESSAGE bundle\_id ...
- 4. OFPT\_BUNDLE\_ADD\_MESSAGE bundle\_id  $modification \ n$
- 5. OFPBCT\_CLOSE\_REQUEST bundle\_id
- 6. OFPBCT\_COMMIT\_REQUEST bundle\_id

The switch is expected to behave as follows. When a bundle is opened, modifications are saved into a temporary staging area without taking effect. When the bundle is committed, the changes in the staging area are applied to the state (e.g. tables) used by the switch. If an error occurs in one modification, no change is applied to the state.

# 6.9.3 Bundle error processing

The OpenFlow messages part of a bundle must be pre-validated before they are stored in the bundle (see 7.3.9.7). For each message sent by the controller, the switch must verify that the syntax of the message is valid and that all features in the message are supported features, and immediately return an error message if this message can not be validated. The switch may optionally verify resource availability and may commit resource at this time and generate errors. Messages generating errors when added to the bundle are not stored in the bundle and the bundle is unmodified.

When the bundle is committed, most errors will have been already detected and reported. One of the message part of the bundle may still fail during commit, for example due to resource availability. In this case, no message part of the bundle is applied and the switch must generate the error message corresponding to the failure (see 7.3.9.9). Messages of a bundle should have unique xid to help matching errors to messages. If none of the messages part of the bundle generate an error message, the switch informs the controller of the successful application of the bundle.

#### 6.9.4 Bundle atomic modifications

Committing the bundle must be controller atomic, i.e. a controller querying the switch must never see the intermediate state, it must see either the state of the switch with none or with all of the modifications contained in the bundle having been applied. In particular, if a bundle fails, controllers should not receive any notification resulting from the partial application of the bundle.

If the flag OFPBF\_ORDERED is specified (see 7.3.9.3), the messages part of the bundle must be applied strictly in order, as if separated by OFPT\_BARRIER\_REQUEST messages (however no OFPT\_BARRIER\_REPLY is generated). If this flag is not specified, messages don't need to be applied in order.

If the flag OFPBF\_ATOMIC is specified (see 7.3.9.3), committing the bundle must also be packet atomic, i.e. a given packet from an input port or packet-out request should either be processed with none or with all of the modifications having been applied. Whether this flag is supported would depend on the switch hardware and software architecture. Packets and messages can temporarily be enqueued while changes are applied. As the resulting increase in forwarding / processing latency may be unacceptable, double buffering techniques are often employed.

If the flag OFPBF\_ATOMIC is not specified, committing the bundle does not need to be packet atomic. Packet may be processed by intermediate state resulting from partial application of the bundle, even if the bundle commit ultimately fails. The various OpenFlow counters would also reflect the partial application of the bundle in this case.

# 6.9.5 Bundle parallelism

The switch must support exchanging echo request and echo reply messages during the creation and population of the bundle, the switch must reply to an echo request without waiting for the end of the bundle. Echo request and echo reply messages can not be included in a bundle. Similarly, asynchronous messages generated by the switch are not impacted by the bundle, the switch must send status events without waiting for the end of the bundle.

If the switch supports multiple controller channels or auxiliary connections, the switch must maintain a separate bundle staging area for each controller-switch connection. This permits multiple bundles to be incrementally populated in parallel on a given switch. The bundle\_id namespace is specific to each controller connection, so that controllers don't need to coordinate.

A switch may also optionally support populating multiple bundle in parallel on the same controller connection, by multiplexing bundle messages with different bundle\_id. The controller may create and send multiple bundles, each identified by a unique bundle\_id, and then can apply any of them in any order by specifying its bundle\_id in a commit message. Inversely, a switch may not allow to create another bundle or accept any regular OpenFlow messages between opening a bundle and either committing it or discarding it.

In some implementations, when a switch starts storing a bundle, it may lock some of the objects referenced by the bundle. If a message on the same or another controller connection tries to modify an object locked by a bundle, the switch must reject that message and return an error. A switch is not required to lock objects referenced by a bundle. If a switch does not lock objects referenced by a bundle, the application of the bundle may fail if those objects have been modified via other controller connections.

## 6.9.6 Scheduled Bundles

A bundle commit request may include an *execution time*, specifying *when* the bundle should be committed. A switch that receives a scheduled bundle, commits the bundle as close as possible to the execution time that was specified in the commit message.

## 6.9.6.1 The Scheduled Bundle Procedure

The scheduled bundle procedure is illustrated in Figure 5:

- 1. The controller starts the bundle procedure by sending an OFPBCT\_OPEN\_REQUEST, and receives a reply from the switch.
- 2. The controller then sends a set of N OFPT\_BUNDLE\_ADD\_MESSAGE messages, for some  $N \geq 1$ .
- 3. The controller may then send an OFPBCT\_CLOSE\_REQUEST. The close request is optional, and thus the controller may skip this step.
- 4. The controller sends an OFPBCT\_COMMIT\_REQUEST. The OFPBCT\_COMMIT\_REQUEST includes the OFPBF\_TIME flag, which indicates whether this is a *scheduled commit*. A scheduled commit request includes the time property, ofp\_bundle\_prop\_time, which contains the scheduled time at which the switch is expected to apply the bundle.
- 5. After receiving the commit message, the switch applies the bundle at the scheduled time,  $T_s$ , and sends a OFPBCT\_COMMIT\_REPLY to the controller.

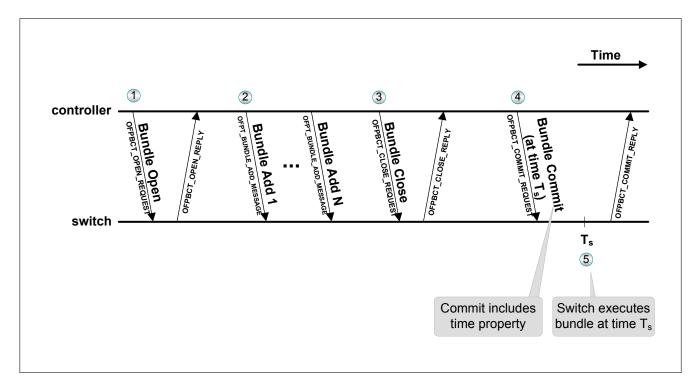

Figure 5: Scheduled Bundle Procedure

#### 6.9.6.2 Discarding Scheduled Bundles

The controller may cancel a scheduled bundle by sending an OFPT\_BUNDLE\_CONTROL message with type OFPBCT\_DISCARD\_REQUEST. An example is shown in Figure 6; if the switch receives the scheduled commit message and is not able to schedule the bundle, it responds to the controller with an error message. This indication may be used for implementing a coordinated update where either all the switches successfully schedule the operation, or the bundle is discarded; when a controller receives a scheduling error message from one of the switches it can send a discard message (step 5' in in Figure 6) to other switches that need to commit a bundle at the same time, and abort the bundle.

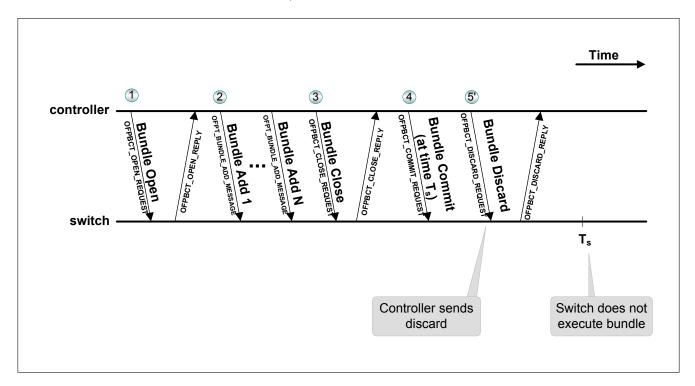

Figure 6: Discarding a Scheduled Commit

## 6.9.6.3 Timekeeping and Synchronization

Every switch that supports scheduled bundles must maintain a clock. It is assumed that clocks are synchronized by a method that is outside the scope of this specification, e.g., the Network Time Protocol (NTP) or the Precision Time Protocol (PTP).

Two factors affect how accurately a switch can commit a scheduled bundle; one factor is the accuracy of the clock synchronization method used to synchronize the switches' clocks, and the second factor is the switch's ability to execute real-time operations, which greatly depends on how it is implemented.

This specification does not define any requirements pertaining to the degree of accuracy of performing scheduled operations. However, every switch that supports the scheduled bundles must be able to report

its estimated scheduling accuracy to the controller. The controller can retrieve this information from the switch using the OFPMP\_BUNDLE\_FEATURES message, defined in Section 7.3.5.20.

Since a switch does not commit a bundle instantaneously, the processing time of required operations should not be overlooked; the scheduled time and execution time always refer to the *start time* of the relevant operation.

# 6.9.6.4 Scheduling Tolerance

When a switch receives a scheduled commit request, it must verify that the scheduled time,  $T_s$ , is not too far in the past or in the future. As illustrated in Figure 7, the switch verifies that  $T_s$  is within the scheduling tolerance range.

The lower bound on  $T_s$  verifies the freshness of the bundle so as to avoid acting upon old and possibly irrelevant messages. Similarly, the upper bound on  $T_s$  guarantees that the switch does not take a long-term commitment to execute a bundle that may become obsolete by the time it is scheduled to be invoked.

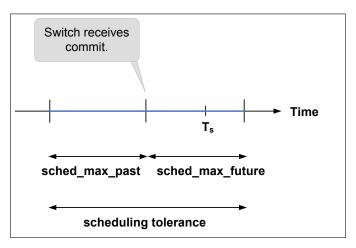

Figure 7: Scheduling Tolerance

The scheduling tolerance is determined by two parameters, sched\_max\_future and sched\_max\_past. The default value of these two parameters is 1 second. The controller may set these fields to a different value using the bundle features request, as described in Section 7.3.5.20.

If the scheduled time,  $T_s$  is within the scheduling tolerance range, the scheduled bundle is committed; if  $T_s$  occurs in the past and within the scheduling tolerance, the switch commits the bundle as soon as possible. If  $T_s$  is a future time, the switch commits the bundle as close as possible to  $T_s$ . If  $T_s$  is not within the scheduling tolerance range, the switch responds to the controller with an error message.

# 7 The OpenFlow Switch Protocol

The heart of the OpenFlow switch specification is the set of structures used for OpenFlow Switch Protocol messages.

#### 7.1 Protocol basic format

The OpenFlow protocol is implemented using OpenFlow messages transmitted over the OpenFlow channel (see 6). Each message type is described by a specific structure, which starts with the common OpenFlow header (see 7.1.1), and the message structure may include other structures which may be common to multiple message types (see 7.2). Each structure defines the order in which information is included in the message and may contain other structures, values, enumerations or bitmasks (see 7.1.3).

The structures, defines, and enumerations described below are derived from the file openflow.h which is included in this document (see Appendix A). Most structures are packed with padding and 8-byte aligned, as checked by the assertion statements (see 7.1.2). All OpenFlow messages are sent in big-endian format.

## 7.1.1 OpenFlow Header

Each OpenFlow message begins with the OpenFlow header:

The version specifies the OpenFlow switch protocol version being used. During the earlier draft phase of the OpenFlow Switch Protocol, the most significant bit was set to indicate an experimental version. The lower bits indicate the revision number of the protocol. The version of the protocol described by the current specification is 1.5.0, and its  $ofp\_version$  is 0x06.

The length field indicates the total length of the message, so no additional framing is used to distinguish one frame from the next. The type can have the following values:

```
enum ofp_type {
   /* Immutable messages. */
   OFPT_HELLO
                           = 0, /* Symmetric message */
   OFPT_ERROR
                           = 1, /* Symmetric message */
   OFPT_ECHO_REQUEST
                           = 2, /* Symmetric message */
   OFPT_ECHO_REPLY
                           = 3, /* Symmetric message */
   OFPT EXPERIMENTER
                           = 4, /* Symmetric message */
   /* Switch configuration messages. */
   OFPT_FEATURES_REQUEST
                          = 5, /* Controller/switch message */
   OFPT_FEATURES_REPLY
                           = 6, /* Controller/switch message */
   OFPT_GET_CONFIG_REQUEST = 7, /* Controller/switch message */
   OFPT GET CONFIG REPLY = 8, /* Controller/switch message */
   OFPT_SET_CONFIG
                           = 9, /* Controller/switch message */
```

```
/* Asynchronous messages. */
OFPT_PACKET_IN
                   = 10, /* Async message */
OFPT_FLOW_REMOVED
                       = 11, /* Async message */
OFPT_PORT_STATUS
                       = 12, /* Async message */
/* Controller command messages. */
OFPT_PACKET_OUT
                       = 13, /* Controller/switch message */
OFPT_FLOW_MOD
                       = 14, /* Controller/switch message */
OFPT_GROUP_MOD
                       = 15, /* Controller/switch message */
OFPT_PORT_MOD
                      = 16, /* Controller/switch message */
OFPT_TABLE_MOD
                       = 17, /* Controller/switch message */
/* Multipart messages. */
OFPT_MULTIPART_REQUEST
                           = 18, /* Controller/switch message */
OFPT_MULTIPART_REPLY
                           = 19, /* Controller/switch message */
/* Barrier messages. */
OFPT_BARRIER_REQUEST
                       = 20, /* Controller/switch message */
OFPT_BARRIER_REPLY
                       = 21, /* Controller/switch message */
/* Controller role change request messages. */
OFPT_ROLE_REQUEST = 24, /* Controller/switch message */
OFPT_ROLE_REPLY
                       = 25, /* Controller/switch message */
/* Asynchronous message configuration. */
OFPT_GET_ASYNC_REQUEST = 26, /* Controller/switch message */
OFPT_GET_ASYNC_REPLY
                       = 27, /* Controller/switch message */
OFPT_SET_ASYNC
                       = 28, /* Controller/switch message */
/* Meters and rate limiters configuration messages. */
OFPT_METER_MOD
                       = 29, /* Controller/switch message */
/* Controller role change event messages. */
OFPT_ROLE_STATUS
                       = 30, /* Async message */
/* Asynchronous messages. */
OFPT_TABLE_STATUS
                      = 31, /* Async message */
/* Request forwarding by the switch. */
                      = 32, /* Async message */
OFPT REQUESTFORWARD
/* Bundle operations (multiple messages as a single operation). */
OFPT_BUNDLE_CONTROL
                    = 33, /* Controller/switch message */
OFPT_BUNDLE_ADD_MESSAGE = 34, /* Controller/switch message */
/* Controller Status async message. */
OFPT_CONTROLLER_STATUS = 35, /* Async message */
```

# 7.1.2 Padding

};

Most OpenFlow messages contain padding fields. Those are included in the various message types and in various common structures. Most of those padding fields can be identified by the fact that their

names start with pad. The goal of padding fields is to align multi-byte entities on natural processor boundaries.

All common structures included in messages are aligned on 64 bit boundaries. Various other types are aligned as needed, for example 32 bits integer are aligned on 32 bit boundaries. An exception to the padding rules are OXM match fields which are never padded (see 7.2.3.2). In general, the end of OpenFlow messages is not padded, unless explicitly specified. On the other hand, common structures are almost always padded at the end.

The padding fields should be set to zero. An OpenFlow implementation must accept any values set in padding fields, and must just ignore the content of padding fields.

# 7.1.3 Reserved and unsupported values and bit positions

Most OpenFlow messages contain enumerations, they are used for example to describe a type, a command or a reason. The specification defines all the values used by this version of the protocol, all other values are reserved, unless explicitly specified. Deprecated values are also reserved. Reserved values should not be used in OpenFlow messages. The specification may also define that the support for some values is optional, so an implementation may not support those optional values. If an OpenFlow implementation receives a request containing a reserved value or an optional value it does not support, it must reject the request and return an appropriate error message. If an OpenFlow implementation receives a reply or asynchronous message containing a reserved value or an optional value it does not support, it should ignore the object containing the unknown value and log an error.

Some messages contain bitmaps (arrays of bits), they are used for example to encode configuration flags, status bits or capabilities. The specification defines all the bit positions used by this version of the protocol, all other bit positions are reserved, unless explicitly specified. Deprecated bit positions are also reserved. Reserved bit positions should bet set to zero in OpenFlow messages. The specification may also define that the support for some bit positions is optional, so an implementation may not support those optional bit positions. If an OpenFlow implementation receives a request containing a reserved bit position or an optional bit position it does not support set to 1, it must reject the request and return an appropriate error message. If an OpenFlow implementation receives a reply or asynchronous message containing a reserved bit position or an optional bit position it does not support set to 1, it should ignore the bit position and log an error.

Some messages contain TLVs (Type, Length, Value). These are used for example to encode properties, actions, match fields or optional attributes in a structure. The specification defines all the TLV types used by this version of the protocol, all other TLV types are reserved, unless explicitly specified. Deprecated TLV types are also reserved. Reserved TLV types should not be used in OpenFlow messages. The specification may also define that the support for some TLV types is optional, so an implementation may not support those optional TLV types. If an OpenFlow implementation receives a request containing a reserved TLV type or an optional TLV type it does not support, it must reject the request and return an appropriate error message. If an OpenFlow implementation receives a reply or asynchronous message containing a reserved TLV type or an optional TLV type it does not support, it should ignore the TLV and log an error.

#### 7.2 Common Structures

This section describes structures used by multiple message types.

#### 7.2.1 Port Structures

The OpenFlow pipeline receives and sends packets on ports. The switch may define physical and logical ports, and the OpenFlow specification defines some reserved ports (see 4.1).

Each port on the switch is uniquely identified by a port number, a 32 bit number. Reserved ports have port number defined by the specification. Port numbers for physical and logical ports are assigned by the switch and can be any numbers starting at 1 and ending at OFPP\_MAX. The port numbers use the following conventions:

```
/* Port numbering. Ports are numbered starting from 1. */
enum ofp_port_no {
   /* Maximum number of physical and logical switch ports. */
   OFPP MAX
                   = 0xffffff00.
    /* Reserved OpenFlow Port (fake output "ports"). */
   OFPP_UNSET
                   = Oxfffffff7, /* Output port not set in action-set.
                                     used only in OXM_OF_ACTSET_OUTPUT. */
   OFPP IN PORT
                   = Oxfffffff8, /* Send the packet out the input port.
                                     reserved port must be explicitly used
                                     in order to send back out of the input
                                     port. */
   OFPP_TABLE
                   = Oxfffffff9, /* Submit the packet to the first flow table
                                     NB: This destination port can only be
                                     used in packet-out messages. */
   OFPP NORMAL
                   = Oxfffffffa, /* Forward using non-OpenFlow pipeline. */
   OFPP_FLOOD
                   = Oxfffffffb, /* Flood using non-OpenFlow pipeline. */
                  = Oxfffffffc, /* All standard ports except input port. */
   OFPP_ALL
   OFPP_CONTROLLER = Oxfffffffd, /* Send to controller. */
   OFPP_LOCAL = Oxfffffffe, /* Local openflow "port". */
                   = Oxffffffff /* Special value used in some requests when
   OFPP_ANY
                                     no port is specified (i.e. wildcarded). */
};
```

#### 7.2.1.1 Port Description Structures

The physical ports, switch-defined logical ports, and the OFPP\_LOCAL reserved port are described with the following structure:

The port\_no field is the port number and it uniquely identifies a port within a switch. The hw\_addr field typically is the MAC address for the port; OFP\_ETH\_ALEN is 6. The name field is a null-terminated string containing a human-readable name for the interface. The value of OFP\_MAX\_PORT\_NAME\_LEN is 16.

The config field describes port administrative settings, and has the following structure:

```
/* Flags to indicate behavior of the physical port. These flags are
 * used in ofp_port to describe the current configuration. They are
 * used in the ofp_port_mod message to configure the port's behavior.
 */
enum ofp_port_config {
    OFPPC_PORT_DOWN = 1 << 0, /* Port is administratively down. */

    OFPPC_NO_RECV = 1 << 2, /* Drop all packets received by port. */
    OFPPC_NO_FWD = 1 << 5, /* Drop packets forwarded to port. */
    OFPPC_NO_PACKET_IN = 1 << 6 /* Do not send packet-in msgs for port. */
};</pre>
```

The OFPPC\_PORT\_DOWN bit indicates that the port has been administratively brought down and should not be used by OpenFlow to send traffic. The OFPPC\_NO\_RECV bit indicates that packets received on that port should be ignored. The OFPPC\_NO\_FWD bit indicates that OpenFlow should not send packets to that port. The OFPPC\_NO\_PACKET\_IN bit indicates that packets on that port that generate a table miss should never trigger a packet-in message to the controller.

In general, the port config bits are set by one of the controllers and not changed by the switch. Those bits may be useful for the controller to implement protocols such as STP or BFD. The port config bits may also be changed by a switch configuration, for example using the OpenFlow Configuration Protocol. If the port config bits are changed on the switch, the switch must send an OFPT\_PORT\_STATUS message to notify the controller of the change.

The state field describes the port internal state, and has the following structure:

```
/* Current state of the physical port. These are not configurable from
 * the controller.
 */
enum ofp_port_state {
    OFPPS_LINK_DOWN = 1 << 0, /* No physical link present. */
    OFPPS_BLOCKED = 1 << 1, /* Port is blocked */
    OFPPS_LIVE = 1 << 2, /* Live for Fast Failover Group. */
};</pre>
```

The port state bits represent the state of the physical link or switch protocols outside of OpenFlow. The OFPPS\_LINK\_DOWN bit indicates the physical link is not present. The OFPPS\_BLOCKED bit indicates that a switch protocol outside of OpenFlow, such as 802.1D Spanning Tree, is preventing the use of that port with OFPP\_FLOOD.

All port state bits are read-only and cannot be changed by the controller. When the port flags are changed, the switch must send an OFPT\_PORT\_STATUS message to notify the controller of the change.

The **properties** field is a list of port description properties, describing various configuration and state of the port.

# 7.2.1.2 Port Description Properties

The list of port description property types that are currently defined are:

A property definition contains the property type, length, and any associated data:

The OFPPDPT\_ETHERNET property uses the following structure and fields:

```
/* Ethernet port description property. */
struct ofp_port_desc_prop_ethernet {
   uint16_t
                            /* OFPPDPT_ETHERNET. */
                   type;
                    length; /* Length in bytes of this property. */
   uint16_t
                   pad[4]; /* Align to 64 bits. */
   uint8_t
   /* Bitmaps of OFPPF_* that describe features. All bits zeroed if
    * unsupported or unavailable. */
   uint32_t curr;
                         /* Current features. */
   uint32_t advertised; /* Features being advertised by the port. */
   uint32_t supported; /* Features supported by the port. */
                         /* Features advertised by peer. */
   uint32_t peer;
   uint32_t curr_speed; /* Current port bitrate in kbps. */
   uint32_t max_speed;
                         /* Max port bitrate in kbps */
OFP_ASSERT(sizeof(struct ofp_port_desc_prop_ethernet) == 32);
```

The curr, advertised, supported, and peer fields indicate link modes (speed and duplexity), link type (copper/fiber) and link features (autonegotiation and pause). Port features are represented by the following structure:

```
/* Features of ports available in a datapath. */
enum ofp_port_features {
   OFPPF_10MB_HD
                   = 1 << 0, /* 10 Mb half-duplex rate support. */
    OFPPF_10MB_FD
                    = 1 << 1, /* 10 Mb full-duplex rate support. */
    OFPPF_100MB_HD = 1 << 2, /* 100 Mb half-duplex rate support. */
    OFPPF_100MB_FD = 1 << 3, /* 100 Mb full-duplex rate support. */
    OFPPF_1GB_HD
                    = 1 << 4, /* 1 Gb half-duplex rate support. */
                    = 1 << 5, /* 1 Gb full-duplex rate support. */
    OFPPF_1GB_FD
                    = 1 << 6, /* 10 Gb full-duplex rate support. */
    OFPPF_10GB_FD
                    = 1 << 7, /* 40 Gb full-duplex rate support. */
    OFPPF_40GB_FD
                    = 1 << 8, /* 100 Gb full-duplex rate support. */
    OFPPF_100GB_FD
                    = 1 << 9, /* 1 Tb full-duplex rate support. */
    OFPPF_1TB_FD
    OFPPF_OTHER
                    = 1 << 10, /* Other rate, not in the list. */
    OFPPF_COPPER
                    = 1 << 11, /* Copper medium. */
    OFPPF_FIBER
                    = 1 << 12, /* Fiber medium. */
    OFPPF_AUTONEG
                    = 1 << 13, /* Auto-negotiation. */
    OFPPF_PAUSE
                    = 1 << 14, /* Pause. */
    OFPPF_PAUSE_ASYM = 1 << 15 /* Asymmetric pause. */
};
```

Multiple of these flags may be set simultaneously. If none of the port speed flags are set, the max\_speed or curr\_speed are used.

The curr\_speed and max\_speed fields indicate the current and maximum bit rate (raw transmission speed) of the link in kbps. The number should be rounded to match common usage. For example, an optical 10 Gb/s Ethernet port should have this field set to 10000000 (instead of 10312500), and an OC-192 port should have this field set to 10000000 (instead of 9953280).

The max\_speed fields indicate the maximum configured capacity of the link, whereas the curr\_speed indicates the current capacity. If the port is a LAG with 3 links of 1 Gb/s capacity, with one of the ports of the LAG being down, one port auto-negotiated at 1 Gb/s and 1 port auto-negotiated at 100 Mb/s, the max\_speed is 3 Gb/s and the curr\_speed is 1.1 Gb/s.

The OFPPDPT\_OPTICAL property uses the following structure and fields:

```
/* Optical port description property. */
struct ofp_port_desc_prop_optical {
   uint16_t
                             /* OFPPDPT_30PTICAL. */
                    type;
                    length; /* Length in bytes of this property. */
   uint16_t
   uint8_t
                    pad[4]; /* Align to 64 bits. */
   uint32_t supported;
                           /* Features supported by the port. */
   uint32_t tx_min_freq_lmda;
                                /* Minimum TX Frequency/Wavelength */
   uint32_t tx_max_freq_lmda;
                                /* Maximum TX Frequency/Wavelength */
   uint32_t tx_grid_freq_lmda; /* TX Grid Spacing Frequency/Wavelength */
   uint32_t rx_min_freq_lmda;
                               /* Minimum RX Frequency/Wavelength */
   uint32_t rx_max_freq_lmda;
                               /* Maximum RX Frequency/Wavelength */
   uint32_t rx_grid_freq_lmda; /* RX Grid Spacing Frequency/Wavelength */
   uint16_t tx_pwr_min;
                                /* Minimum TX power */
```

The minimum, maximum, and grid spacing are specified for both transmit and receive optical ports as either a frequency in MHz or wavelength (lambda) as nm \* 100. For ports that are not tunable, the minimum and maximum values will be identical and specify the fixed value. The tx\_pwr\_min and tx\_pwr\_max are dBm \* 10. The optical port features are specified as follows:

```
/* Features of optical ports available in switch. */
enum ofp_optical_port_features {
    OFPOPF_RX_TUNE = 1 << 0, /* Receiver is tunable */
    OFPOPF_TX_TUNE = 1 << 1, /* Transmit is tunable */
    OFPOPF_TX_PWR = 1 << 2, /* Power is configurable */
    OFPOPF_USE_FREQ = 1 << 3, /* Use Frequency, not wavelength */
};</pre>
```

The OFPOPF\_RX\_TUNE indicates the port receive function is able to tune, the OFPOPF\_TX\_TUNE indicates the port transmit function is able to tune. The OFPOPF\_TX\_PWR indicates the transmit power can be set. The OFPOPF\_USE\_FREQ indicates frequency must be used instead of wavelength for description of the port tuning. It is highly important that the same tuning domain (frequency or wavelength) is used as indicated, since conversion between wavelength and frequency is often prone to error due to the range of the values.

The OFPPDPT\_PIPELINE\_INPUT and OFPPDPT\_PIPELINE\_OUTPUT properties uses the following structure and fields:

```
/* Ingress or egress pipeline fields. */
struct ofp_port_desc_prop_oxm {
                              /* One of OFPPDPT_PIPELINE_INPUT or
   uint16_t
                    type;
                                 OFPPDPT_PIPELINE_OUTPUT. */
    uint16 t
                    length; /* Length in bytes of this property. */
    /* Followed by:
         - Exactly (length - 4) bytes containing the oxm_ids, then
         - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
                    oxm_ids[0];
                                 /* Array of OXM headers */
    uint32_t
};
OFP_ASSERT(sizeof(struct ofp_port_desc_prop_oxm) == 4);
```

The oxm\_ids is a list of OXM types supported by the port (see 7.2.3.2). The elements of that list are 32-bit OXM headers for non-experimenter OXM fields or 64-bit OXM headers for experimenter OXM fields, those OXM fields don't include any payload. The oxm\_length field in OXM headers must be the length value defined for the OXM field, i.e. the payload length if the OXM field had a payload. For experimenter OXM fields with variable payload size, the oxm\_length field must be the maximum length of the payload.

The OFPPDPT\_PIPELINE\_INPUT property indicates the list of pipeline fields that are provided for packets received on the port (see 7.2.3.7). The port sets those pipeline fields with useful values on the packets

it receives based on internal processing. If <code>OXM\_OF\_IN\_PORT</code> in the only pipeline field supported, this property does not need to be included.

The OFPPDPT\_PIPELINE\_OUTPUT property indicates the list of pipeline fields that are consumed by the port for packets that are output on that port (see 7.2.3.7). The port uses the values set in those pipeline fields for internal processing when forwarding packet. If no pipeline field is supported, this property does not need to be included.

The OFPPDPT RECIRCULATE property uses the following structure and fields:

```
/* Recirculate port description property. */
struct ofp_port_desc_prop_recirculate {
                               /* OFPPDPT_RECIRCULATE. */
    uint16_t
                type;
    uint16_t
                 length;
                               /* Length in bytes of the property,
                                   including this header, excluding padding. */
    /* Followed by:
        - Exactly (length - 4) bytes containing the port numbers, then
        - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
                port_nos[0];
                                 /* List of recirculated input port numbers.
    uint32_t
                                    O or more. The number of port numbers
                                    is inferred from the length field in
                                    the header. */
};
OFP_ASSERT(sizeof(struct ofp_port_desc_prop_recirculate) == 4);
```

The port\_nos field is the list of input ports where a packet output on the present port can be recirculated back into the OpenFlow pipeline (see 4.7). This property must be used only when the port recirculates packets back to the OpenFlow pipeline, other ports must not used this property. For a loopback or unidirectional service returning on the same port, this field would only include the present port number. For an encapsulation/decapsulation service or other bidirectional services, this field would include the other port number representing the other side of the service. If the recirculation can return via an arbitrary port number, the list would be empty.

The OFPPDPT\_EXPERIMENTER property uses the following structure and fields:

```
/* Experimenter port description property. */
struct ofp_port_desc_prop_experimenter {
                              /* OFPPDPT_EXPERIMENTER. */
   uint16_t
                     type;
    uint16_t
                     length; /* Length in bytes of this property. */
    uint32_t
                     experimenter; /* Experimenter ID which takes the same
                                       form as in struct
                                       ofp_experimenter_header. */
    uint32_t
                                    /* Experimenter defined. */
                     exp_type;
    /* Followed by:
         - Exactly (length - 12) bytes containing the experimenter data, then
         - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
                     experimenter_data[0];
    uint32_t
};
OFP_ASSERT(sizeof(struct ofp_port_desc_prop_experimenter) == 12);
```

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8).

# 7.2.2 Header Types Structure

Headers types are used to identify the various header sections of the packet header. A header type is defined using the ofp\_header\_type structure:

The namespace field identifies the namespace used for the header type. Most namespaces are well known packet type lists managed outside the OpenFlow protocol.

The ns\_type field is the packet type within the chosen namespace. The definition of that field depends on the namespace.

The following namespaces are defined:

- OFPHTN\_ONF is the ONF namespace. For this namespace, ns\_type is one of the values defined below.
- OFPHTN\_ETHERTYPE is the Ethertype namespace. For this namespace, ns\_type is an Ethertype, as defined by the IEEE Standards Association.
- OFPHTN\_IP\_PROTO is the IP protocol namespace. For this namespace, ns\_type is a IP protocol number, as defined by the IETF. Only the lower 8 bits of ns\_type are significant, the high order bits must be set to zero.
- OFPHTN\_UDP\_TCP\_PORT is the TCP UDP port namespace. For this namespace, ns\_type is a TCP or UDP port number, as defined by the IETF.
- OFPHTN\_IPV4\_OPTION is the IPv4 option namespace. For this namespace, ns\_type is a IPv4 option number, as defined by the IETF. Only the lower 8 bits of ns\_type are significant, the high order bits must be set to zero.

The following values for ns type in the ONF namespace are defined:

- OFPHTO\_ETHERNET is a basic Ethernet header, as defined by the combination of the Ethernet DIX standard and the IEEE 802.3 standard. It contains a source address, a destination address and an Ethertype.
- OFPHTO\_NO\_HEADER is an empty header. It is used when no packet header can be used, for example
  for circuit switches.
- OFPHTO\_OXM\_EXPERIMENTER reference to a OXM experimenter value. If a header type equal to OFPHTO\_OXM\_EXPERIMENTER is used in a list of OXM values, the header type is defined by the first OXM experimenter value following it (see 7.2.3.12). This allows experimenters to define any arbitrary header types.

Most parts of the packet headers can be identified by their **header type**, i.e. the tuple (namespace, ns\_type). A specific part of the packet headers may have multiple header types, for example one in each namespace. The **canonical header type** of common headers is defined in Table 9. For headers not listed in that table, the **canonical header type** is the header type with the smallest namespace number, and within a single namespace the header type with the smallest ns\_type number.

namespace	$ns_{-}type$	Header definition	non-canonical
0	0	Ethernet header: IEEE Std 802.3.	(1, 0x6558)
0	1	No header.	
1	0x800	IPv4 header: RFC 791. (2, 0x4)	
1	0x8100	VLAN tag: IEEE Std 802.1Q. (1, 0x88a8)	
1	0x86dd	IPv6 header: RFC 2460. (2, 0x29)	
1	0x8847	MPLS shim header: RFC 3032.	(1, 0x8848), (2, 0x89)
1	0x88E7	PBB I-TAG: IEEE std 802.1Q.	
2	6	Basic TCP header: RFC 793.	
2	17	UDP header: RFC 768.	
3	4789	VxLAN header: RFC 7348.	

Table 9: Common Canonical Header Types.

#### 7.2.3 Flow Match Structures

The OpenFlow match structure is used for matching packets (see 5.3) or matching flow entries in the table (see 5.2). It is composed of a flow match header and a sequence of zero or more flow match fields encoded using OXM TLVs.

#### 7.2.3.1 Flow Match Header

The flow match header is described by the ofp\_match structure:

```
* - Exactly (length - 4) (possibly 0) bytes containing OXM TLVs, then
* - Exactly ((length + 7)/8*8 - length) (between 0 and 7) bytes of
* all-zero bytes
* In summary, ofp_match is padded as needed, to make its overall size
* a multiple of 8, to preserve alignement in structures using it.
*/
uint8_t oxm_fields[0];    /* 0 or more OXM match fields */
uint8_t pad[4];    /* Zero bytes - see above for sizing */
};
OFP_ASSERT(sizeof(struct ofp_match) == 8);
```

The type field is set to OFPMT\_OXM and length field is set to the actual length of ofp\_match structure including all match fields. The payload of the OpenFlow match is a set of OXM Flow match fields.

The only valid match type in this specification is OFPMT\_OXM. The OpenFlow 1.1 match type OFPMT\_STANDARD is deprecated. If an alternate match type is used, the match fields and payload may be set differently, but this is outside the scope of this specification.

# 7.2.3.2 Flow Match Field Structures

The flow match fields are described using the OpenFlow Extensible Match (OXM) format, which is a compact type-length-value (TLV) format. Each OXM TLV is 5 to 259 (inclusive) bytes long. OXM TLVs are not aligned on or padded to any multibyte boundary. The first 4 bytes of an OXM TLV are its header, followed by the entry's body.

An OXM TLV's header is interpreted as a 32-bit word in network byte order (see figure 8).

Figure 8: OXM TLV header layout.

The OXM TLV's header fields are defined in Table 10

The oxm\_class is a OXM match class that contains related match types, and is described in section 7.2.3.3. oxm\_field is a class-specific value, identifying one of the match types within the match class.

Name		Width	Usage	
oxm_type	oxm_class	16	Match class: member class or reserved class	
	oxm_field	7	Match field within the class	
	oxm_hasmask	1	Set if OXM includes a bitmask in payload	
	oxm_length	8	Length of OXM payload	

Table 10: OXM TLV header fields.

The combination of oxm\_class and oxm\_field (the most-significant 23 bits of the header) are collectively oxm\_type. The oxm\_type normally designates a protocol header field, such as the Ethernet type, but it can also refer to a packet pipeline field, such as the switch port on which a packet arrived.

oxm hasmask defines if the OXM TLV contains a bitmask, more details are explained in section 7.2.3.5.

oxm\_length is a positive integer describing the length of the OXM TLV payload in bytes. The length of the OXM TLV, including the header, is exactly  $4 + \text{oxm_length}$  bytes.

For a given oxm\_class, oxm\_field, and oxm\_hasmask value, oxm\_length is a constant. It is included only to allow software to minimally parse OXM TLVs of unknown types. (Similarly, for a given oxm\_class, oxm\_field, and oxm\_length, oxm\_hasmask is a constant.)

#### 7.2.3.3 OXM classes

The match types are structured using OXM match classes. The OpenFlow specification distinguishes two types of OXM match classes, ONF member classes and ONF reserved classes, differentiated by their high order bit. Classes with the high order bit set to 1 are ONF reserved classes, they are used for the OpenFlow specification itself. Classes with the high order bit set to zero are ONF member classes, they are allocated by the ONF on an as needed basis, they uniquely identify an ONF member and can be used arbitrarily by that member. Support for ONF member classes is optional.

The following OXM classes are defined:

```
/* OXM Class IDs.
 * The high order bit differentiate reserved classes from member classes.
 * Classes 0x0000 to 0x7FFF are member classes, allocated by ONF.
 * Classes 0x8000 to 0xFFFE are reserved classes, reserved for standardisation.
 */
enum ofp_oxm_class {
                          = 0x0000,
    OFPXMC_NXM_O
                                       /* Backward compatibility with NXM */
    OFPXMC_NXM_1
                          = 0x0001,
                                       /* Backward compatibility with NXM */
    OFPXMC_OPENFLOW_BASIC = 0x8000,
                                       /* Basic class for OpenFlow */
    OFPXMC_PACKET_REGS
                         = 0x8001,
                                       /* Packet registers (pipeline fields). */
    OFPXMC_EXPERIMENTER
                        = OxFFFF,
                                       /* Experimenter class */
};
```

The class OFPXMC\_OPENFLOW\_BASIC contains the basic set of OpenFlow match fields (see 7.2.3.7). The optional class OFPXMC\_PACKET\_REGS contains packet registers (see 7.2.3.10). The optional class OFPXMC\_EXPERIMENTER is used for experimenter matches (see 7.2.3.12), it differs from other classes because it includes an experimenter header between the OXM TLV header and the value in the payload.

Other ONF reserved classes are reserved for future uses such as modularisation of the specification. The first two ONF member classes OFPXMC\_NXM\_0 and OFPXMC\_NXM\_1 are reserved for backward compatibility with the Nicira Extensible Match (NXM) specification.

### 7.2.3.4 Flow Matching

A zero-length OpenFlow match (one with no OXM TLVs) matches every packet. Match fields that should be wildcarded are omitted from the OpenFlow match.

An OXM TLV places a constraint on the packets matched by the OpenFlow match:

- If oxm\_hasmask is 0, the OXM TLV's body contains a value for the field, called oxm\_value. The OXM TLV match matches only packets in which the corresponding field equals oxm\_value.
- If oxm\_hasmask is 1, then the oxm\_entry's body contains a value for the field (oxm\_value), followed by a bitmask of the same length as the value, called oxm\_mask. Each 1-bit in oxm\_mask constrains the OXM TLV to match only packets in which the corresponding bit of the field equals the corresponding bit in oxm\_value. Each 0-bit in oxm\_mask places no constraint on the corresponding bit in the field.

When using masking, it is an error for a 0-bit in oxm\_mask to have a corresponding 1-bit in oxm\_value (see 7.5.4.5).

The following table summarizes the constraint that a pair of corresponding oxm\_mask and oxm\_value bits place upon the corresponding field bit when using masking. Omitting oxm\_mask is equivalent to supplying an oxm\_mask that is all 1-bits.

	oxm_va	lue
$oxm_mask$	0	1
0	no constraint	error
1	must be 0	must be 1

Table 11: OXM mask and value.

When there are multiple OXM TLVs, all of the constraints must be met: the packet fields must match all OXM TLVs part of the OpenFlow match. The fields for which OXM TLVs that are not present are wildcarded to ANY, omitted OXM TLVs are effectively fully masked to zero.

#### 7.2.3.5 Flow Match Field Masking

When oxm\_hasmask is 1, the OXM TLV contains a bitmask that follows the field value, it has the same size as the field value and is encoded in the same way. For fields not in the experimenter class, this means that oxm\_length is effectively doubled, so oxm\_length is always even when oxm\_hasmask is 1. For fields in the experimenter class, the experimenter header is not duplicated, the length increase corresponds only to the size of the mask, and the resulting oxm\_length depends on the experimenter header used.

The masks are defined such that a 0 in a given bit position indicates a "don't care" match for the same bit in the corresponding field, whereas a 1 means match the bit exactly. An all-zero-bits oxm\_mask is

equivalent to omitting the OXM TLV entirely. An all-one-bits oxm\_mask is equivalent to specifying 0 for oxm\_hasmask and omitting oxm\_mask.

Some oxm\_types may not support masked wildcards, that is, oxm\_hasmask must always be 0 when these fields are specified. For example, the field that identifies the ingress port on which a packet was received may not be masked.

Some oxm\_types that do support masked wildcards may only support certain oxm\_mask patterns. For example, some fields that have IPv4 address values may be restricted to CIDR masks (subnet masks).

These restrictions are detailed in specifications for individual fields. A switch may accept an oxm\_hasmask or oxm\_mask value that the specification disallows, but only if the switch correctly implements support for that oxm\_hasmask or oxm\_mask value. A switch must reject an attempt to set up a flow entry that contains a oxm hasmask or oxm mask value that it does not support (see 6.4).

# 7.2.3.6 Flow Match Field Prerequisite

The presence of an OXM TLV with a given oxm\_type may be restricted based on the presence or values of other OXM TLVs, its prerequisites. In general, matching header fields of a protocol can only be done if the OpenFlow match explitly matches the corresponding protocol.

# For example:

- An OXM TLV for oxm\_type=OXM\_OF\_IPV4\_SRC is allowed only if it is preceded by another entry with oxm\_type=OXM\_OF\_ETH\_TYPE, oxm\_hasmask=0, and oxm\_value=0x0800. That is, matching on the IPv4 source address is allowed only if the Ethernet type is explicitly set to IPv4.
- An OXM TLV for oxm\_type=OXM\_OF\_TCP\_SRC is allowed only if it is preceded by an entry with oxm\_type=OXM\_OF\_ETH\_TYPE, oxm\_hasmask=0, oxm\_value=0x0800 or 0x86dd, and another with oxm\_type=OXM\_OF\_IP\_PROTO, oxm\_hasmask=0, oxm\_value=6, in that order. That is, matching on the TCP source port is allowed only if the Ethernet type is IP and the IP protocol is TCP.
- An OXM TLV for oxm\_type=OXM\_OF\_MPLS\_LABEL is allowed only if it is preceded by an entry with oxm\_type=OXM\_OF\_ETH\_TYPE, oxm\_hasmask=0, oxm\_value=0x8847 or 0x8848.
- An OXM TLV for oxm\_type=OXM\_OF\_VLAN\_PCP is allowed only if it is preceded by an entry with oxm\_type=OXM\_OF\_VLAN\_VID, oxm\_value!=OFPVID\_NONE.

The prerequisite of a match field is another match field type and match field value that this match field depends on. Most match fields have prerequisites, these restrictions are noted in specifications for individual fields (see 7.2.3.8). The prerequisites are cumulative, a match field inherits all the restrictions of its prerequisites (see examples above), and all the chains of prerequisites must be present in the match.

A switch may implement relaxed versions of these restrictions. For example, a switch may accept no prerequisite at all. A switch must reject an attempt to set up a flow entry that violates its restrictions (see 7.5.4.5), and must deal with inconsistent matches created by the lack of prerequisites (for example matching both a TCP source port and a UDP destination port).

New match fields defined by members (in member classes or as experimenter fields) may provide alternate prerequisites to already specified match fields. For example, this could be used to reuse existing IP match fields over an alternate link technology (such as PPP) by substituting the ETH\_TYPE prerequisite as needed (for PPP, that could be a hypothetical PPP\_PROTOCOL field).

An OXM TLV that has prerequisite restrictions must appear after the OXM TLVs for its prerequisites. Ordering of OXM TLVs within an OpenFlow match is not otherwise constrained (apart from the Packet Type Match Field).

Any given oxm\_type may appear in an OpenFlow match at most once, otherwise the switch must generate an error (see 7.5.4.5). A switch may implement a relaxed version of this rule and may allow in some cases an oxm\_type to appear multiple times in an OpenFlow match, however the behaviour of matching is then implementation-defined.

If a flow table implements a specific OXM TLV, this flow table must accept valid matches containing the prerequisites of this OXM TLV, even if the flow table does not support matching all possible values for the match fields specified by those prerequisites. For example, if a flow table matches the IPv4 source address, this flow table must accept matching the Ethertype exactly to IPv4, however this flow table does not need to support matching Ethertype to any other value.

#### 7.2.3.7 Flow Match Fields

The specification defines a default set of match fields with oxm\_class=OFPXMC\_OPENFLOW\_BASIC which can have the following values:

```
/* OXM Flow match field types for OpenFlow basic class. */
enum oxm_ofb_match_fields {
    OFPXMT_OFB_IN_PORT
                             = 0, /* Switch input port. */
    OFPXMT_OFB_IN_PHY_PORT
                             = 1, /* Switch physical input port. */
    OFPXMT_OFB_METADATA
                             = 2, /* Metadata passed between tables. */
    OFPXMT_OFB_ETH_DST
                             = 3, /* Ethernet destination address. */
    OFPXMT_OFB_ETH_SRC
                              = 4, /* Ethernet source address. */
    OFPXMT_OFB_ETH_TYPE
                             = 5, /* Ethernet frame type. */
    OFPXMT_OFB_VLAN_VID
                             = 6, /* VLAN id. */
    OFPXMT_OFB_VLAN_PCP
                             = 7, /* VLAN priority. */
                             = 8, /* IP DSCP (6 bits in ToS field). */
    OFPXMT_OFB_IP_DSCP
                             = 9, /* IP ECN (2 bits in ToS field). */
    OFPXMT_OFB_IP_ECN
    OFPXMT_OFB_IP_PROTO
                             = 10, /* IP protocol. */
    OFPXMT_OFB_IPV4_SRC
                             = 11, /* IPv4 source address. */
    OFPXMT_OFB_IPV4_DST
                             = 12, /* IPv4 destination address. */
    OFPXMT_OFB_TCP_SRC
                             = 13, /* TCP source port. */
                             = 14, /* TCP destination port. */
    OFPXMT_OFB_TCP_DST
    OFPXMT_OFB_UDP_SRC
                             = 15, /* UDP source port. */
    OFPXMT_OFB_UDP_DST
                             = 16, /* UDP destination port. */
    OFPXMT_OFB_SCTP_SRC
                             = 17, /* SCTP source port. */
    OFPXMT_OFB_SCTP_DST
                             = 18, /* SCTP destination port. */
                             = 19, /* ICMP type. */
    OFPXMT_OFB_ICMPV4_TYPE
    OFPXMT_OFB_ICMPV4_CODE
                             = 20, /* ICMP code. */
                             = 21, /* ARP opcode. */
    OFPXMT_OFB_ARP_OP
                             = 22, /* ARP source IPv4 address. */
    OFPXMT_OFB_ARP_SPA
    OFPXMT_OFB_ARP_TPA
                             = 23, /* ARP target IPv4 address. */
    OFPXMT_OFB_ARP_SHA
                             = 24, /* ARP source hardware address. */
```

```
OFPXMT_OFB_ARP_THA
                              = 25, /* ARP target hardware address. */
    OFPXMT_OFB_IPV6_SRC
                              = 26, /* IPv6 source address. */
    OFPXMT_OFB_IPV6_DST
                              = 27, /* IPv6 destination address. */
    OFPXMT_OFB_IPV6_FLABEL
                              = 28, /* IPv6 Flow Label */
    OFPXMT_OFB_ICMPV6_TYPE
                              = 29, /* ICMPv6 type. */
    OFPXMT_OFB_ICMPV6_CODE
                              = 30, /* ICMPv6 code. */
    OFPXMT_OFB_IPV6_ND_TARGET = 31, /* Target address for ND. */
    OFPXMT_OFB_IPV6_ND_SLL
                              = 32, /* Source link-layer for ND. */
    OFPXMT_OFB_IPV6_ND_TLL
                              = 33, /* Target link-layer for ND. */
    OFPXMT_OFB_MPLS_LABEL
                              = 34, /* MPLS label. */
    OFPXMT_OFB_MPLS_TC
                              = 35, /* MPLS TC. */
                              = 36, /* MPLS BoS bit. */
    OFPXMT_OFP_MPLS_BOS
    OFPXMT_OFB_PBB_ISID
                              = 37, /* PBB I-SID. */
    OFPXMT_OFB_TUNNEL_ID
                              = 38, /* Logical Port Metadata. */
    OFPXMT_OFB_IPV6_EXTHDR
                              = 39, /* IPv6 Extension Header pseudo-field */
                              = 41, /* PBB UCA header field. */
    OFPXMT_OFB_PBB_UCA
    OFPXMT_OFB_TCP_FLAGS
                              = 42, /* TCP flags. */
                              = 43, /* Output port from action set metadata. */
    OFPXMT_OFB_ACTSET_OUTPUT
    OFPXMT_OFB_PACKET_TYPE
                              = 44, /* Packet type value. */
};
```

Field		Description
OXM_OF_IN_PORT	Required in ingress	Ingress port. This may be a physical or logical port.
OXM_OF_ACTSET_OUTPUT	Required in egress	Egress port from action set.
OXM_OF_ETH_DST	Required	Ethernet destination address. Can use arbitrary bitmask
OXM_OF_ETH_SRC	Required	Ethernet source address. Can use arbitrary bitmask
OXM_OF_ETH_TYPE	Required	Ethernet type of the OpenFlow packet payload, after VLAN
		tags.
OXM_OF_IP_PROTO	Required	IPv4 or IPv6 protocol number
OXM_OF_IPV4_SRC	Required	IPv4 source address. Can use subnet mask or arbitrary bit-
		mask
OXM_OF_IPV4_DST	Required	IPv4 destination address. Can use subnet mask or arbitrary
		bitmask
OXM_OF_IPV6_SRC	Required	IPv6 source address. Can use subnet mask or arbitrary bit-
		mask
OXM_OF_IPV6_DST	Required	IPv6 destination address. Can use subnet mask or arbitrary
		bitmask
OXM_OF_TCP_SRC	Required	TCP source port
OXM_OF_TCP_DST	Required	TCP destination port
OXM_OF_UDP_SRC	Required	UDP source port
OXM_OF_UDP_DST	Required	UDP destination port

Table 12: Required match fields.

A switch that supports Ethernet packet types must support the required match fields listed in Table 12 in its pipeline. Each required match field must be supported in at least one flow table of the switch: that flow table must enable matching that field and the match field prerequisites must be met in that table (see 7.2.3.6). The required fields don't need to be implemented in all flow tables, and don't need

to be implemented in the same flow table. Flow tables can support non-required and experimenter match fields. The controller can query the switch about which match fields are supported in each flow table (see 7.3.5.18).

Match fields come in two types, header match fields (see 7.2.3.8) and pipeline match fields (see 7.2.3.9).

# 7.2.3.8 Header Match Fields

Header match fields are match fields matching values extracted from the packet headers. Most header match fields map directly to a specific field in the packet header defined by a datapath protocol.

All header match fields have different size, prerequisites and masking capability, as specified in Table 13. If not explicitly specified in the field description, each field type refers to the outermost occurrence of the field in the packet headers.

Field	Bits	Bytes	Mask	Pre-requisite	Description
OXM_OF_ETH_DST	48	6	Yes	$PACKET_TYPE=(0,0)$ or	Ethernet destination MAC address.
				None	
OXM_OF_ETH_SRC	48	6	Yes	PACKET_TYPE=(0,0) or	Ethernet source MAC address.
				None	
OXM_OF_ETH_TYPE	16	2	No	$PACKET_TYPE=(0,0)$ or	Ethernet type of the OpenFlow packet pay-
				None	load, after VLAN tags.
OXM_OF_VLAN_VID	12+1	2	Yes	$PACKET\_TYPE=(0,0)$ or	VLAN-ID from 802.1Q header. The CFI bit
				None	indicates the presence of a valid VLAN-ID,
					see below.
OXM_OF_VLAN_PCP	3	1	No	VLAN_VID!=NONE	VLAN-PCP from 802.1Q header.
OXM_OF_IP_DSCP	6	1	No	ETH_TYPE=0x0800 or	Diff Serv Code Point (DSCP). Part of the
				ETH_TYPE=0x86dd or	IPv4 ToS field or the IPv6 Traffic Class field.
				PACKET_TYPE=(1,0x800)	
				or	
				PACKET_TYPE=(1,0x86dd)	
OXM_OF_IP_ECN	2	1	No	ETH_TYPE=0x0800 or	ECN bits of the IP header. Part of the IPv4
				ETH_TYPE=0x86dd or	ToS field or the IPv6 Traffic Class field.
				PACKET_TYPE=(1,0x800)	
				or	
				PACKET_TYPE=(1,0x86dd)	
OXM_OF_IP_PROTO	8	1	No	ETH_TYPE=0x0800 or	IPv4 or IPv6 protocol number.
				ETH_TYPE=0x86dd or	
				PACKET_TYPE=(1,0x800)	
				or	
				PACKET_TYPE=(1,0x86dd)	
OXM_OF_IPV4_SRC	32	4	Yes	ETH_TYPE=0x0800 or	IPv4 source address. Can use subnet mask or
				PACKET_TYPE=(1,0x800)	arbitrary bitmask
OXM_OF_IPV4_DST	32	4	Yes	ETH_TYPE=0x0800 or	IPv4 destination address. Can use subnet
				PACKET_TYPE=(1,0x800)	mask or arbitrary bitmask
OXM_OF_TCP_SRC	16	2	No	IP_PROTO=6	TCP source port
OXM_OF_TCP_DST	16	2	No	IP_PROTO=6	TCP destination port
OXM_OF_TCP_FLAGS	12	2	Yes	IP_PROTO=6	TCP flags
OXM_OF_UDP_SRC	16	2	No	IP_PROTO=17	UDP source port
OXM_OF_UDP_DST	16	2	No	IP_PROTO=17	UDP destination port
OXM_OF_SCTP_SRC	16	2	No	IP_PROTO=132	SCTP source port
OXM_OF_SCTP_DST	16	2	No	IP_PROTO=132	SCTP destination port
OXM_OF_ICMPV4_TYPE	8	1	No	IP_PROTO=1	ICMP type
OXM_OF_ICMPV4_CODE	8	1	No	IP_PROTO=1	ICMP code
OXM_OF_ARP_OP	16	2	No	ETH_TYPE=0x0806	ARP opcode
	1		Ta	ble 13 – continued on next page	_

Field	Bits	Bytes	Mask	Pre-requisite	Description
OXM_OF_ARP_SPA	32	4	Yes	ETH_TYPE=0x0806	Source IPv4 address in the ARP payload.
					Can use subnet mask or arbitrary bitmask
OXM_OF_ARP_TPA	32	4	Yes	ETH_TYPE=0x0806	Target IPv4 address in the ARP payload.
					Can use subnet mask or arbitrary bitmask
OXM_OF_ARP_SHA	48	6	Yes	ETH_TYPE=0x0806	Source Ethernet address in the ARP payload.
OXM_OF_ARP_THA	48	6	Yes	ETH_TYPE=0x0806	Target Ethernet address in the ARP payload.
OXM_OF_IPV6_SRC	128	16	Yes	ETH_TYPE=0x86dd or	IPv6 source address. Can use subnet mask or
				PACKET_TYPE=(1,0x86dd)	arbitrary bitmask
OXM_OF_IPV6_DST	128	16	Yes	ETH_TYPE=0x86dd or	IPv6 destination address. Can use subnet
				PACKET_TYPE=(1,0x86dd)	mask or arbitrary bitmask
OXM_OF_IPV6_FLABEL	20	4	Yes	ETH_TYPE=0x86dd or	IPv6 flow label.
				PACKET_TYPE=(1,0x86dd)	
OXM_OF_ICMPV6_TYPE	8	1	No	IP_PROTO=58	ICMPv6 type
OXM_OF_ICMPV6_CODE	8	1	No	IP_PROTO=58	ICMPv6 code
OXM_OF_IPV6_ND_TARGET	128	16	No	ICMPV6_TYPE=135 or	The target address in an IPv6 Neighbor Dis-
				ICMPV6_TYPE=136	covery message.
OXM_OF_IPV6_ND_SLL	48	6	No	ICMPV6_TYPE=135	The source link-layer address option in an
					IPv6 Neighbor Discovery message.
OXM_OF_IPV6_ND_TLL	48	6	No	ICMPV6_TYPE=136	The target link-layer address option in an
					IPv6 Neighbor Discovery message.
OXM_OF_MPLS_LABEL	20	4	No	ETH_TYPE=0x8847 or	The LABEL in the first MPLS shim header.
				ETH_TYPE=0x8848	
OXM_OF_MPLS_TC	3	1	No	ETH_TYPE=0x8847 or	The TC in the first MPLS shim header.
				ETH_TYPE=0x8848	
OXM_OF_MPLS_BOS	1	1	No	ETH_TYPE=0x8847 or	The BoS bit (Bottom of Stack bit) in the first
				ETH_TYPE=0x8848	MPLS shim header.
OXM_OF_PBB_ISID	24	3	Yes	ETH_TYPE=0x88E7	The I-SID in the first PBB service instance
					tag.
OXM_OF_IPV6_EXTHDR	9	2	Yes	ETH_TYPE=0x86dd or	IPv6 Extension Header pseudo-field.
				PACKET_TYPE=(1,0x86dd)	
OXM_OF_PBB_UCA	1	1	No	ETH_TYPE=0x88E7	The UCA field in the first PBB service in-
					stance tag.

Table 13 – concluded from previous page

Table 13: Header match fields details.

Omitting the OFPXMT\_OFB\_VLAN\_VID field specifies that a flow entry should match packets regardless of whether they contain the corresponding tag. Special values are defined below for the VLAN tag to allow matching of packets with any tag, independent of the tag's value, and to support matching packets without a VLAN tag. The special values defined for OFPXMT\_OFB\_VLAN\_VID are:

```
/* The VLAN id is 12-bits, so we can use the entire 16 bits to indicate
 * special conditions.
 */
enum ofp_vlan_id {
    OFPVID_PRESENT = 0x1000, /* Bit that indicate that a VLAN id is set */
    OFPVID_NONE = 0x0000, /* No VLAN id was set. */
};
```

The OFPXMT\_OFB\_VLAN\_PCP field must be rejected when the OFPXMT\_OFB\_VLAN\_VID field is wildcarded (not present) or when the value of OFPXMT\_OFB\_VLAN\_VID is set to OFPVID\_NONE. Table 14 summarizes the combinations of wildcard bits and field values for particular VLAN tag matches.

OXM field	oxm_value	oxm_mask	Matching packets
absent	-	-	Packets with and without a VLAN tag
present	OFPVID_NONE	absent	Only packets without a VLAN tag
present	OFPVID_PRESENT	OFPVID_PRESENT	Only packets with a VLAN tag regardless of its
			value
present	value   OFPVID_PRESENT	absent	Only packets with VLAN tag and VID equal
			value

Table 14: Match combinations for VLAN tags.

The field OXM\_OF\_IPV6\_EXTHDR is a pseudo header match field that indicates the presence of various IPv6 extension headers in the packet header. The IPv6 extension header bits are combined together in the fields OXM\_OF\_IPV6\_EXTHDR, and those bits can have the following values:

```
/* Bit definitions for IPv6 Extension Header pseudo-field. */
enum ofp_ipv6exthdr_flags {
    OFPIEH_NONEXT = 1 << 0,
                                /* "No next header" encountered. */
                                /* Encrypted Sec Payload header present. */
    OFPIEH_ESP
                 = 1 << 1,
    OFPIEH_AUTH
                  = 1 << 2,
                                /* Authentication header present. */
    OFPIEH_DEST
                 = 1 << 3,
                                /* 1 or 2 dest headers present. */
    OFPIEH_FRAG
                  = 1 << 4,
                                /* Fragment header present. */
    OFPIEH_ROUTER = 1 << 5,
                                /* Router header present. */
    OFPIEH_HOP
                  = 1 << 6,
                                /* Hop-by-hop header present. */
    OFPIEH_UNREP = 1 << 7,
                               /* Unexpected repeats encountered. */
    OFPIEH_UNSEQ = 1 << 8,
                                /* Unexpected sequencing encountered. */
};
```

- OFPIEH\_HOP is set to 1 if a hop-by-hop IPv6 extension header is present as the first extension header in the packet.
- OFPIEH\_ROUTER is set to 1 if a router IPv6 extension header is present.
- OFPIEH FRAG is set to 1 if a fragmentation IPv6 extension header is present.
- OFPIEH\_DEST is set to 1 if one or more Destination options IPv6 extension headers are present. It is normal to have either one or two of these in one IPv6 packet (see RFC 2460).
- OFPIEH AUTH is set to 1 if an Authentication IPv6 extension header is present.
- OFPIEH\_ESP is set to 1 if an Encrypted Security Payload IPv6 extension header is present.
- OFPIEH NONEXT is set to 1 if a No Next Header IPv6 extension header is present.
- OFPIEH\_UNSEQ is set to 1 if IPv6 extension headers were not in the order preferred (but not required) by RFC 2460.
- OFPIEH\_UNREP is set to 1 if more than one of a given IPv6 extension header is unexpectedly encountered. (Two destination options headers may be expected and would not cause this bit to be set.)

The field OXM\_OF\_TCP\_FLAGS matches the flag bits in a TCP header. Considering bit 0 the least significant bit, it specifically contains:

• Bits 0–5: The original TCP flags defined in RFC 793.

- Bits 6–8: Additional TCP flags defined by RFCs 3168 and 3540.
- Bits 9–11: Reserved bits not yet standardized by RFCs.
- Bits 12–15: Not part of the OXM field, forced to zero. (The TCP header uses the corresponding bits for other purposes, so they will never be standardized as flags.)

### 7.2.3.9 Pipeline Match Fields

Pipeline match fields are match fields matching values attached to the packet for pipeline processing and not associated with packet headers.

All pipeline match fields have different size, prerequisites and masking capability, as specified in Table 15.

Field	Bits	Bytes	Mask	Pre-requisite	Description
OXM_OF_IN_PORT	32	4	No	None	Ingress port. Numerical representation of incom-
					ing port, starting at 1. This may be a physical or
					switch-defined logical port.
OXM_OF_IN_PHY_PORT	32	4	No	IN_PORT present	Physical port. In ofp_packet_in messages, under-
					lying physical port when packet received on a log-
					ical port.
OXM_OF_METADATA	64	8	Yes	None	Table metadata. Used to pass information between
					tables.
OXM_OF_TUNNEL_ID	64	8	Yes	None	Metadata associated with a logical port.
OXM_OF_ACTSET_OUTPUT	32	4	No	None	Output port from action set Metadata or
					OFPP_UNSET.
OXM_OF_PACKET_TYPE	16+16	4	No	None	Packet type - canonical header type of outermost
					header.

Table 15: Pipeline match fields details.

The ingress port field OXM\_OF\_IN\_PORT is used to match the OpenFlow port on which the packet was received in the OpenFlow datapath. It can either be a physical, a logical port, the OFPP\_LOCAL reserved port or the OFPP\_CONTROLLER reserved port (see 4.1). The ingress port must be a valid standard OpenFlow port or the OFPP\_CONTROLLER reserved port, and for standard ports the port configuration must allow it to receive packets (both OFPPC\_PORT\_DOWN and OFPPC\_NO\_RECV config bits cleared).

The physical port field OXM\_OF\_IN\_PHY\_PORT is used in *Packet-in* messages to identify a physical port underneath a logical port (see 7.4.1). Some switches may optionally allow to match this field in flow entries. The physical port does not need to have any specific configuration, for example it can be down. The physical port does not need to be a valid standard port, it can be a port not included in the port description request (see 7.3.5.6).

When a packet is received directly on a physical port and not processed by a logical port, OXM\_OF\_IN\_PORT and OXM\_OF\_IN\_PHY\_PORT have the same value, the OpenFlow port\_no of this physical port (see 4.1). When a packet is received on a logical port by way of a physical port, OXM\_OF\_IN\_PORT is the logical port's port\_no and OXM\_OF\_IN\_PHY\_PORT is the physical port's port\_no. For example, consider a packet received on a tunnel interface defined over a link aggregation group (LAG) with two physical port members. If the tunnel interface is the logical port bound to OpenFlow, then

OXM\_OF\_IN\_PORT is the tunnel's port\_no and OXM\_OF\_IN\_PHY\_PORT is the physical port\\_no member of the LAG on which the tunnel is configured.

The metadata field OXM\_OF\_METADATA is used to pass information between lookups across multiple tables. This value can be arbitrarily masked.

The Tunnel ID field OXM\_OF\_TUNNEL\_ID carries optional encapsulation metadata associated with a logical port. When a packet is received on a logical port that supports Tunnel ID, the Tunnel ID field associated with the packet is set with the encapsulation metadata and can be matched by flow entries. If the logical port does not provide such data or if the packet was received on a physical port, its value is zero. When a packet is sent on a logical port that supports the tunnel-id field, it will use the value of that field for internal encapsulation processing. For example, that field may be set by a flow entry using a set-field action.

If a logical port supports the Tunnel ID field, either provides it on input, consumes it on output, or both, it should report that support in the corresponding port description property (see 7.2.1.2).

The mapping of the optional encapsulation metadata in the Tunnel ID field is defined by the logical port implementation, it is dependant on the type of logical port and it is implementation specific. We recommend that for a packet received via a GRE tunnel including a (32-bit) key, the key is stored in the lower 32-bits and the high bits are zeroed. We recommend that for a MPLS logical port, the lower 20 bits represent the MPLS Label. We recommend that for a VxLAN logical port, the lower 24 bits represent the VNI.

The Action Set Output field OXM\_OF\_ACTSET\_OUTPUT can be used to match the output action embedded in the action set of the packet, and in most cases can be used to match packets based on their output port. All flow tables used as egress tables are required to support this field, flow tables used as ingress tables may optionally support that field, depending on switch capabilities. If the action set contains an output action and no group action, this field equals the output port from that action. Otherwise, if the action set does not contain an output action, or contains a group action, the field equals its initial value, OFPP\_UNSET.

### 7.2.3.10 Packet registers

The packet register fields OXM\_OF\_PKT\_REG(N) are used to store temporary values and information alongside the packet through pipeline processing. Each packet register is 64 bit wide and maskable. In most cases, the packet registers can not be matched in tables, i.e. they usually can not be used in the flow entry match structure. They can be used with the *set-field* and *copy-field* actions (see 7.2.6.7 and 7.2.6.8).

A switch may optionally implement any number of packet registers, up to the limit of the OXM format (i.e. 128). Each packet register is identified by its OXM type field. If a switch supports packet registers and uses contiguous numbering starting at zero, only the supported packet register with the greatest field number needs to be listed in the table feature properties, otherwise all supported packet registers must be individually listed (see 7.3.5.18.2). A switch that does not support packet register fields must not include any packet register entry in the table feature properties.

# 7.2.3.11 Packet Type Match Field

The Packet Type Match Field is a pipeline field with OXM type OXM\_OF\_PACKET\_TYPE, its value identifies a packet type in the datapath. The value of common packet types is defined in Table 16. For other packet types, the value must be the canonical header type of the packet outermost header (see 7.2.2). The Packet Type Match Field must appear as the first OXM TLV, and only matches packets of that specific type. Most Packet Type values are also prerequisites for other match fields. If a Packet Type Match Field is not present, the packet type must be Ethernet.

The Packet Types defined by the specification are listed in Table 16. New Packet Types can be defined using other canonical header types or the Experimenter mechanism (see 7.2.2). Most switches will support only a single Packet Type, support for multiple Packet Types is currently outside this specification (but may be added in a future version).

namespace	$ns\_type$	Match description	Packet-in and packet-out for-
			mat
0	0	Ethernet packet (default type).	Ethernet header and Ethernet pay-
			load.
1	0x800	IPv4 packet (with no header in	IPv4 header and IPv4 payload.
		front).	
1	0x86dd	IPv6 packet (with no header in	IPv6 header and IPv6 payload.
		front).	
0	1	No packet (for example circuit	Empty.
		switch).	
0	0xFFFF	Experimenter defined.	Experimenter defined.

Table 16: Packet Types.

An OpenFlow switch that supports a specific packet type advertises the corresponding Packet Type Match Field in the *table feature properties* (see 7.3.5.18.2). *Flow-mod* messages must include the proper Packet Type Match Field in the match, unless the packet type is Ethernet (see 7.3.4.2). *Packet-in* messages must include the Packet Type Match Field in the match, unless the packet type is Ethernet (see 7.4.1). *Packet-out* messages must include the Packet Type Match Field in the match, unless the packet type is Ethernet (see 7.3.6).

The Packet Type (0, 0) is the packet type for Ethernet packets. For this packet type, the match may include, for example, the Ethernet destination address, Ethernet source address, Ethertype, and other match fields based on the Ethertype. For this packet type, the packet-in and packet-out data field includes the Ethernet headers and the Ethernet payload of an Ethernet frame, but does not include the preamble, the start of frame, the Ethernet FCS/CRC and the interframe gap. This packet type would typically be used in Ethernet switches.

The Packet Type (1, 0x800) is the packet type for IPv4 packets. For this packet type, the match may include, for example, IPv4 destination and source addresses, IP protocol and other match fields based on the protocol. For this packet type, the packet-in and packet-out data field includes the IPv4 header and the IPv4 payload of the IPv4 datagram. For example, this packet type may be used in IP routers.

The Packet Type (1, 0x86dd) is the packet type for IPv6 packets. For this packet type, the match may include, for example, IPv6 destination and source addresses, IP protocol and other match fields based

on the protocol. For this packet type, the packet-in and packet-out data field includes the IPv6 header and the IPv6 payload of the IPv6 datagram. For example, this packet type may be used in IP routers.

The Packet Type (0, 1) is the packet type for tables that don't match packets. For this packet type, the match only includes pipeline match fields, pseudo-header fields and does not include any real header fields. For example, this packet type may be used in circuit switches.

The Packet Type (0, 0xFFFF) is the packet type for Experimenter packet types. The actual packet type is defined by the first OXM experimenter value following it (see 7.2.3.12). This allows experimenters to define arbitrary packet types.

# 7.2.3.12 Experimenter Flow Match Fields

Support for experimenter-specific flow match fields is optional. Experimenter-specific flow match fields may be defined using the oxm\_class=OFPXMC\_EXPERIMENTER.

The oxm\_class field in the OXM header must be set to OFPXMC\_EXPERIMENTER.

The oxm\_field field in the OXM header is the experimenter type, which is experimenter managed (see 7.2.8). Together, the experimenter identifier and the experimenter type identifies the experimenter match field.

The experimenter field is encoded in the first four bytes of the OXM TLV's body. It contains the experimenter identifier, which takes the same form as in the typical experimenter structure (see 7.2.8).

The rest of the OXM TLV body is experimenter-defined and does not need to be padded or aligned.

#### 7.2.4 Flow Stats Structures

An OpenFlow stats is composed of a flow stats header and a sequence of zero or more flow stat fields.

# 7.2.4.1 Flow Stats Header

The flow stats header is described by the ofp\_stats structure:

```
/* Flow statistics structure - list of statistic fields. */
struct ofp_stats {
   uint16_t reserved;
                              /* Reserved for future use, currently zeroed. */
   uint16_t length;
                              /* Length of ofp_stats (excluding padding) */
   /* Followed by:
        - Exactly (length - 4) (possibly 0) bytes containing OXS TLVs, then
        - Exactly ((length + 7)/8*8 - length) (between 0 and 7) bytes of
          all-zero bytes
    * In summary, ofp_stats is padded as needed, to make its overall size
    * a multiple of 8, to preserve alignement in structures using it.
   uint8_t oxs_fields[0];
                           /* 0 or more OXS stat fields */
   uint8_t pad[4];
                              /* Zero bytes - see above for sizing */
};
OFP_ASSERT(sizeof(struct ofp_stats) == 8);
```

The length field is set to the actual length of ofp\_stats structure including all stat fields. The payload of the OpenFlow stats is a set of OXS Flow stat fields.

#### 7.2.4.2 Flow Stat Field Structures

The flow stat fields are described using the OpenFlow Extensible Stat (OXS) format, which is a compact type-length-value (TLV) format. Each OXS TLV is 5 to 259 (inclusive) bytes long. OXS TLVs are not aligned on or padded to any multibyte boundary. The first 4 bytes of an OXS TLV are its header, followed by the entry's body.

An OXS TLV's header is interpreted as a 32-bit word in network byte order (see figure 9).

31	16 15	9 8 7	0
$oxs\_class$	oxs_field	res	$oxs\_length$

Figure 9: OXS TLV header layout.

The OXS TLV's header fields are defined in Table 17

	Name	Width	$\mathbf{U}\mathbf{sage}$
oxs_type	oxs_class	16	Stat class: member class or reserved class
oxs_type	oxs_field	7	Stat field within the class
	oxs_reserved	1	Reserved for future use
	oxs_length	8	Length of OXS payload

Table 17: OXS TLV header fields.

The oxs\_class is a OXS stat class that contains related stat types, and is described in section 7.2.4.3. oxs\_field is a class-specific value, identifying one of the stat types within the stat class. The combination of oxs\_class and oxs\_field (the most-significant 23 bits of the header) are collectively oxs\_type. The oxs\_type normally designates a statistic field, such as flow byte count.

oxs\_reserved is reserved for future use and must be set to zero.

oxs\_length is a positive integer describing the length of the OXS TLV payload in bytes. The length of the OXS TLV, including the header, is exactly 4 + oxs\_length bytes.

For a given oxs\_class, oxs\_field, and oxs\_reserved value, oxs\_length is a constant. It is included only to allow software to minimally parse OXS TLVs of unknown types. (Similarly, for a given oxs\_class, oxs\_field, and oxs\_length, oxs\_reserved is a constant.)

#### 7.2.4.3 OXS classes

The stat types are structured using OXS stat classes. Those follow the same convention as the OXM match classes (see 7.2.3.3). The following OXS classes are defined:

The class OFPXSC\_OPENFLOW\_BASIC contains the basic set of OpenFlow stat fields (see 7.2.4.4). The optional class OFPXSC\_EXPERIMENTER is used for experimenter stat fields (see 7.2.4.5).

#### 7.2.4.4 Flow Stat Fields

The specification defines a default set of stat fields with oxs\_class=OFPXSC\_OPENFLOW\_BASIC which can have the following values:

Each flow table of the switch must support the required stat fields listed in Table 18. Optional stat fields must be included in the ofp\_stats structure only if they are supported by the flow table; if the flow table does not support them, they can't be included in ofp\_stats structure.

All stat fields have different size, as specified in Table 18.

Field	Bits	Flow entry	Aggregate	Description
OXS_OF_DURATION	2*32	Required	Undefined	Time flow entry has been alive.
OXS_OF_IDLE_TIME	2*32	Optional	Undefined	Time flow entry has been idle.
OXS_OF_FLOW_COUNT	32	Undefined	Required	Number of aggregated flow entries.
OXS_OF_PACKET_COUNT	64	Optional	Optional	Number of packets matched by a flow entry.
OXS_OF_BYTE_COUNT	64	Optional	Optional	Number of bytes matched by a flow entry.

Table 18: Stat fields details.

The OXS\_OF\_DURATION field indicates the elapsed time the flow entry has been installed in the switch. The first 32 bit value in the payload is duration\_sec and the second 32 bit value is duration\_nsec. The total duration in nanoseconds can be computed as  $duration\_sec \times 10^9 + duration\_nsec$ . Implementations are required to provide second precision; higher precision is encouraged where available. This field is not defined for OFPMP\_AGGREGATE replies and should not be used in that case.

The OXS\_OF\_IDLE\_TIME field indicates the elapsed time for which the flow entry has not matched any packets, and is the value that would be used by the switch to compare against the flow entry idle\_timeout (see 7.3.4.2). The encoding of this time value is identical to the OXS\_OF\_DURATION field. This field is not defined for OFPMP\_AGGREGATE replies and should not be used in that case.

The OXS\_OF\_FLOW\_COUNT field is only used in OFPMP\_AGGREGATE replies and indicates how many flow entries match the request (see 7.3.5.4). This field is not defined for flow entries (i.e. outside of OFPMP\_AGGREGATE replies) and should not be used in those cases.

The OXS\_OF\_PACKET\_COUNT field is the number of packets matched by a flow entry. In OFPMP\_AGGREGATE replies, it is the number of packets matched by all the flow entries matching the request.

The OXS\_OF\_BYTE\_COUNT field is the number of bytes in packets matched by a flow entry. In OFPMP\_AGGREGATE replies, it is the number of bytes matched by all the flow entries matching the request.

#### 7.2.4.5 Experimenter Flow Stat Fields

Support for experimenter-specific flow stat fields is optional. Experimenter-specific flow stat fields may be defined using the oxs\_class=OFPXSC\_EXPERIMENTER.

The oxs\_class field in the OXS header must be set to OFPXMC\_EXPERIMENTER.

The oxs\_field field in the OXS header is the experimenter type, which is experimenter managed (see 7.2.8). Together, the experimenter identifier and the experimenter type identifies the experimenter stat field.

The experimenter field is encoded in the first four bytes of the OXS TLV's body. It contains the experimenter identifier, which takes the same form as in the typical experimenter structure (see 7.2.8).

The rest of the OXS TLV body is experimenter-defined and does not need to be padded or aligned.

#### 7.2.5 Flow Instruction Structures

Flow instructions associated with a flow table entry are executed when a flow matches the entry. The list of instructions that are currently defined are:

```
enum ofp_instruction_type {
    OFPIT_GOTO_TABLE = 1,
                               /* Setup the next table in the lookup
                                  pipeline */
    OFPIT_WRITE_METADATA = 2, /* Setup the metadata field for use later in
                                  pipeline */
    OFPIT_WRITE_ACTIONS = 3,
                               /* Write the action(s) onto the datapath action
                                  set */
    OFPIT_APPLY_ACTIONS = 4,
                               /* Applies the action(s) immediately */
    OFPIT_CLEAR_ACTIONS = 5,
                             /* Clears all actions from the datapath
                                  action set */
    OFPIT_DEPRECATED = 6,
                               /* Deprecated (was apply meter) */
    OFPIT_STAT_TRIGGER = 7,
                              /* Statistics triggers */
    OFPIT_EXPERIMENTER = OxFFFF /* Experimenter instruction */
};
```

The instruction set is described in section 5.5. Flow tables may support a subset of instruction types. An instruction definition contains the instruction type, length, and any associated data:

The OFPIT GOTO TABLE instruction uses the following structure and fields:

table\_id indicates the next table in the packet processing pipeline.

The OFPIT\_WRITE\_METADATA instruction uses the following structure and fields:

Metadata for the next table lookup can be written using the metadata and the metadata\_mask in order to set specific bits on the match field. If this instruction is not specified, the metadata is passed, unchanged.

The OFPIT\_WRITE\_ACTIONS, OFPIT\_APPLY\_ACTIONS, and OFPIT\_CLEAR\_ACTIONS instructions use the following structure and fields:

For the Apply-Actions instruction, the actions field is treated as a list and the actions are applied to the packet *in-order* (see 5.7).

For the Write-Actions instruction, the actions field is treated as a set and the actions are merged into the current action set (see 5.6). If the set of actions contains two actions of the same type or two set-field actions of the same type, the switch can either return an error (see 7.5.4.3), or the switch can merge the set of actions in the action set *in-order*, with the later action of the set of actions overwriting earlier actions of the same type (see 5.6).

For the Clear-Actions instruction, the structure does not contain any actions.

The OFPIT\_STAT\_TRIGGER instruction uses the following structure and fields:

The flags field is a bitmap that defines the behaviour of the statistic trigger. It may include a combination of the following flags:

```
enum ofp_stat_trigger_flags {
    OFPSTF_PERIODIC = 1 << 0, /* Trigger for all multiples of thresholds. */
    OFPSTF_ONLY_FIRST = 1 << 1, /* Trigger on only first reach threshold. */
};</pre>
```

When the OFPSTF\_PERIODIC flag is set, the trigger will apply not only on the values in the thresholds, but also on all multiples of those values. It allows for example to have a trigger every 100 packets for the lifetime of the flow.

When the OFPSTF\_ONLY\_FIRST is set, only the first threshold that is crossed is considered, and other thresholds are ignored. It allows to get only a single trigger for multiple thresholds.

The thresholds is a list of statistic field thresholds. When one of the statistic field values of the flow entry crosses its threshold a *stat trigger* event is sent to the controller. The flow entry is unmodified by this operation. For example, if the threshold list includes a byte count of 10000, when the flow entry byte count goes from 9000 to 10500, a message must be generated.

When a *stat trigger* event must be sent to the controller, the switch must add a flow stats entry with reason OFPFSR\_STAT\_TRIGGER in a flow stats multipart message (see 7.3.5.3), and that message must be sent to the controller. A flow stats multipart message may contain multiple unrelated *stat trigger* events to reduce overhead on the control channel. The switch may drop or delay any *stat trigger* event due to congestion and backup on the control channel or to optimise usage of the control channel. A controller is strongly advised to use this instruction in such a way that the event rate is manageable by the switch.

An OFPIT\_EXPERIMENTER instruction uses the following structure and fields:

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8). The rest of the instruction body is experimenter defined, the whole instruction need to be padded to 64 bits.

#### 7.2.6 Action Structures

A number of actions may be associated with flow entries, groups or packets. The currently defined action types are:

```
next-to-outermost */
   OFPAT_SET_MPLS_TTL = 15, /* MPLS TTL */
   OFPAT_DEC_MPLS_TTL = 16, /* Decrement MPLS TTL */
                      = 17, /* Push a new VLAN tag */
   OFPAT_PUSH_VLAN
   OFPAT_POP_VLAN
                      = 18, /* Pop the outer VLAN tag */
   OFPAT_PUSH_MPLS
                      = 19, /* Push a new MPLS tag */
   OFPAT POP MPLS
                     = 20, /* Pop the outer MPLS tag */
   OFPAT_SET_QUEUE
                      = 21, /* Set queue id when outputting to a port */
   OFPAT_GROUP
                      = 22, /* Apply group. */
   OFPAT_SET_NW_TTL = 23, /* IP TTL. */
   OFPAT_DEC_NW_TTL = 24, /* Decrement IP TTL. */
   OFPAT_SET_FIELD
                     = 25, /* Set a header field using OXM TLV format. */
                      = 26, /* Push a new PBB service tag (I-TAG) */
   OFPAT_PUSH_PBB
   OFPAT_POP_PBB
                      = 27, /* Pop the outer PBB service tag (I-TAG) */
   OFPAT_COPY_FIELD = 28, /* Copy value between header and register. */
   OFPAT_METER
                      = 29, /* Apply meter (rate limiter) */
   OFPAT_EXPERIMENTER = Oxffff
};
```

Output, group, and set-queue actions are described in Section 5.8, tag push/pop actions are described in Table 2, and Set-Field actions are described from their OXM types in Table 13.

Actions are used in flow entry instructions and in group buckets. The use of an action that modifies the packet assumes that a corresponding set of headers exists in the packet. The effect of an action on a packet that does not have the corresponding set of headers is undefined (switch and field dependent). For example, using a pop VLAN action on a packet that does not have a VLAN tag, or using a set TTL on a packet without IP or MPLS header, are undefined. The switch may optionally reject flow entries for which an action is inconsistent with the match structure and prior actions of the flow entry (see 6.4). Controllers are strongly encouraged to avoid generating combinations of table entries that may yield inconsistent actions.

An action definition contains the action type, length, and any associated data:

#### 7.2.6.1 Output Action Structures

An Output action uses the following structure and fields:

```
/* Action structure for OFPAT_OUTPUT, which sends packets out 'port'.
   * When the 'port' is the OFPP_CONTROLLER, 'max_len' indicates the max
   * number of bytes to send. A 'max_len' of zero means no bytes of the
   * packet should be sent. A 'max_len' of OFPCML_NO_BUFFER means that
   * the packet is not buffered and the complete packet is to be sent to
```

The port specifies the port through which the packet should be sent. The max\_len indicates the maximum amount of data from a packet that should be sent when the port is OFPP\_CONTROLLER. If max\_len is zero, the switch must send zero bytes of the packet. A max\_len of OFPCML\_NO\_BUFFER means that the complete packet should be sent, and it should not be buffered.

# 7.2.6.2 Group Action Structures

A *Group* action uses the following structure and fields:

The group\_id indicates the group used to process this packet. The set of buckets to apply depends on the group type.

# 7.2.6.3 Set-Queue Action Structure

The Set-Queue action sets the queue id that will be used to map a flow entry to an already-configured queue on a port, regardless of the IP DSCP and VLAN PCP bits. The packet should not change as a result of a Set-Queue action. If the switch needs to set the DSCP/PCP bits for internal handling, the original values should be restored before sending the packet out.

A switch may support only queues that are tied to specific PCP/DSCP bits. In that case, we cannot map an arbitrary flow entry to a specific queue, therefore the Set-Queue action is not supported. The user can still use these queues and map flow entries to them by setting the relevant fields (IP DSCP, VLAN PCP), however the mapping from DSCP or PCP to the queues is implementation specific.

A Set Queue action uses the following structure and fields:

#### 7.2.6.4 Meter Action Structure

The *Meter* action uses the following structure and fields:

meter\_id indicates which meter to apply on the packet.

#### 7.2.6.5 TTL Actions Structures

A Set MPLS TTL action uses the following structure and fields:

The mpls\_ttl field is the MPLS TTL to set.

A Decrement MPLS TTL action takes no arguments and consists only of a generic ofp\_action\_generic. The action decrements the MPLS TTL.

A Set Network TTL action uses the following structure and fields:

The nw\_ttl field is the TTL address to set in the IP header.

A Decrement Network TTL action takes no arguments and consists only of a generic ofp\_action\_generic. This action decrements the TTL in the IP header if one is present.

A Copy TTL outwards action takes no arguments and consists only of a generic ofp\_action\_generic. The action copies the TTL from the next-to-outermost header with TTL to the outermost header with TTL.

A Copy TTL inwards action takes no arguments and consists only of a generic ofp\_action\_generic. The action copies the TTL from the outermost header with TTL to the next-to-outermost header with TTL.

# 7.2.6.6 Push and Pop Actions Structures

The Push VLAN header, Push MPLS header and Push PBB header actions use the following structure and fields:

The ethertype field indicates the Ethertype of the new tag. It is used when pushing a new VLAN tag, new MPLS header or PBB service header to identify the type of the new header, and it must be valid for that tag type.

The Push tag actions *always* insert a new tag header in the outermost valid location for that tag, as defined by the specifications governing that tag.

The *Push VLAN header* action pushes a new VLAN tag onto the packet (C-TAG or S-TAG). When a new VLAN tag is pushed, it should be the outermost tag inserted, immediately after the Ethernet header and before other tags. The **ethertype** field must be 0x8100 or 0x88a8.

The *Push MPLS header* action pushes a new MPLS shim header onto the packet. When a new MPLS tag is pushed on an IP packet, it is the outermost MPLS tag, inserted as a shim header immediately

before any MPLS tags or immediately before the IP header, whichever comes first. The ethertype field must be 0x8847 or 0x8848.

The Push PBB header action logically pushes a new PBB service instance header onto the packet (I-TAG TCI), and copies the original Ethernet addresses of the packet into the customer addresses (C-DA and C-SA) of the tag. The PBB service instance header should be the outermost tag inserted, immediately after the Ethernet header and before other tags. The ethertype field must be 0x88E7. The customer addresses of the I-TAG are in the location of the original Ethernet addresses of the encapsulated packet, therefore this action can be seen as adding both the backbone MAC-in-MAC header and the I-SID field to the front of the packet. The Push PBB header action does not add a backbone VLAN header (B-TAG) to the packet, it can be added via the Push VLAN header action after the push PBB header operation. After this operation, regular set-field actions can be used to modify the outer Ethernet addresses (B-DA and B-SA).

A *Pop VLAN header* action takes no arguments and consists only of a generic ofp\_action\_generic. The action pops the outermost VLAN tag from the packet.

A Pop PBB header action takes no arguments and consists only of a generic ofp\_action\_generic. The action logically pops the outer-most PBB service instance header from the packet (I-TAG TCI) and copies the customer addresses (C-DA and C-SA) in the Ethernet addresses of the packet. This action can be seen as removing the backbone MAC-in-MAC header and the I-SID field from the front of the packet. The Pop PBB header action does not remove the backbone VLAN header (B-TAG) from the packet, it should be removed prior to this operation via the Pop VLAN header action.

A Pop MPLS header action uses the following structure and fields:

The ethertype indicates the Ethertype of the MPLS payload. The ethertype is used as the Ethertype for the resulting packet regardless of whether the "bottom of stack (BoS)" bit was set in the removed MPLS shim. It is recommended that flow entries using this action match both the MPLS label and the MPLS BoS fields to avoid applying the wrong Ethertype to the MPLS payload.

The MPLS specification does not allow setting an arbitrary Ethertype to MPLS payload when BoS is not equal to 1, and the controller is responsible in complying with this requirement and only set 0x8847 or 0x8848 as the Ethertype for those MPLS payloads. The switch can optionally enforce this MPLS requirement: in this case the switch should reject any flow entry matching a wildcard BoS and any flow entry matching BoS to 0 with the wrong ethertype in the Pop MPLS header action, and in both cases should return a *Match Inconsistent* error message (see 7.5.4.3).

### 7.2.6.7 Set-Field Action Structure

The Set Field actions use the following structure and fields:

The field contains a header field described using a single OXM TLV structure (see 7.2.3). Set-Field actions are defined by oxm\_type, the type of the OXM TLV, and modify the corresponding header field or pipeline field of the packet with the value of oxm\_value, the payload of the OXM TLV, and optionally using a bitmask oxm\_mask if oxm\_hasmask is set.

The type of a *set-field* action is one of the valid OXM header type. The list of possible OXM types are described in Section 7.2.3.7 and Table 13. All header match fields are valid in the set-field action, except for OXM\_OF\_IPV6\_EXTHDR. The pipeline fields OXM\_OF\_METADATA, OXM\_OF\_TUNNEL\_ID and all OXM\_OF\_PKT\_REG(N) are valid in the set-field action, other pipeline fields, OXM\_OF\_IN\_PORT and OXM\_OF\_IN\_PHY\_PORT are not valid in the set-field action.

The value of oxm\_value indicates the value to write in the packet header or pipeline field. When masking is not used, the value in the payload of the OXM TLV must be valid, in particular bits of the payload not defined by the OXM type must be set to zero. When masking is used, the bits of oxm\_value that correspond to a 0-bit in oxm\_mask must be set to 0, and the remaining bits must form a valid modification of the field. In an OXM\_OF\_VLAN\_VID set-field action, the OFPVID\_PRESENT bit must be a 1-bit in oxm\_value and in oxm\_mask.

The value of oxm\_hasmask is used to indicate that the action contains a bitmask for the value. This feature is optional and can only be used if the switch indicated its availability (see 7.3.5.18.2), otherwise an error must be generated (see 7.5.4.3). If oxm\_hasmask is 0, the full header field is set to oxm\_value. If oxm\_hasmask is 1, then the oxm\_entry's body contains a value for the field (oxm\_value), followed by a bitmask of the same length as the value, called oxm\_mask. For each 1-bit in oxm\_mask, the corresponding bit of header field is set with the corresponding bit from oxm\_value. For each 0-bit in oxm\_mask, the corresponding bit of header field is preserved.

When using masking, it is an error for a 0-bit in oxm\_mask to have a corresponding 1-bit in oxm\_value (see 7.5.4.3).

When the Set-Field action changes a header field, it overwrites the actual packet header field in the packet specified by the OXM type, and it performs the necessary CRC recalculation based on the header field. The OXM field refers to the outermost-possible occurrence in the header, unless the field

type explicitly specifies otherwise, and therefore in general the set-field actions apply to the outermost-possible header (e.g. a "Set VLAN ID" set-field action always sets the ID of the outermost VLAN tag).

The OXM prerequisites (see 7.2.3.6) corresponding to the field to be set must be included in the flow entry, otherwise an error must be generated (see 7.5.4.3). Each prerequisite either must be included in the match of the flow entry or must be met through an action occurring before the set-field action (for example pushing a tag). The use of a set-field action assumes that the corresponding header field exists in the packet, the effect of a set-field action on a packet that does not have the corresponding header field is undefined (switch and field dependant). In particular, when setting the VID on a packet without a VLAN header, a switch may or may not automatically add a new VLAN tag, and the controller must explicitly use a Push VLAN header action to be compatible with all switch implementations. Controllers are strongly encouraged to avoid generating combinations of table entries that may yield inconsistent set-field actions.

#### 7.2.6.8 Copy-Field Action Structure

The Copy Field action uses the following structure and fields:

```
/* Action structure for OFPAT_COPY_FIELD. */
struct ofp_action_copy_field {
    uint16_t type;
                                    /* OFPAT_COPY_FIELD. */
    uint16_t len;
                                    /* Length is padded to 64 bits. */
    uint16_t n_bits;
                                    /* Number of bits to copy. */
    uint16_t src_offset;
                                    /* Starting bit offset in source. */
    uint16_t dst_offset;
                                    /* Starting bit offset in destination. */
    uint8_t pad[2];
                                    /* Align to 32 bits. */
    /* Followed by:
        - Exactly 8, 12 or 16 bytes containing the oxm_ids, then
        - Enough all-zero bytes (either 0 or 4) to make the action a whole
           multiple of 8 bytes in length */
    uint32 t
                     oxm ids[0];
                                  /* Source and destination OXM headers */
};
OFP_ASSERT(sizeof(struct ofp_action_copy_field) == 12);
```

Copies src\_oxm\_id[src\_offset:src\_offset+n\_bits] to dst\_oxm\_id[dst\_offset:dst\_offset+n\_bits], where a[b:c] denotes the bits within 'a' numbered 'b' through 'c' (not including bit 'c'). Bit numbering starts at 0 for the least-significant bit, 1 for the next most significant bit, and so on.

The n\_bits field contains the number of bits to copy from src\_oxm\_id into dst\_oxm\_id.

The src\_offset field indicates the bit offset in src\_oxm\_id where bits should be read.

The dst\_offset field indicates the bit offset in dst\_oxm\_id where bits should be written.

The oxm\_ids field is a list containing two OXM types. The first element of this list, src\_oxm\_id, identifies the header or pipeline field where the value is copied from. The second element of this list, dst\_oxm\_id, identifies the header or pipeline field where the value is copied to. The elements of that list are 32-bit OXM headers for non-experimenter OXM fields or 64-bit OXM headers for experimenter OXM fields, those OXM fields don't include any payload. The value of oxm\_hasmask must be zero and no value or mask is included. If the Copy Field action is supported, it must support src\_oxm\_id

or dst\_oxm\_id being one of the packet registers supported by the switch. Support for other pipeline fields and header fields is optional, for those fields this action must obey the same rules as the Set Field action, in particular with respect to prerequisites.

The switch must reject Copy Field actions for which src\_offset+n\_bits is greater than the width of src\_oxm\_id or dst\_offset+n\_bits is greater than the width of dst\_oxm\_id with a Bad Set Argument error message (see 7.5.4.3). This action must behave properly when src\_oxm\_id overlaps with dst\_oxm\_id, that is, it behaves as if src\_oxm\_id were copied out to a temporary buffer, then the temporary buffer copied to dst\_oxm\_id, if this is not possible the switch must reject the Copy Field action with a Bad Set Type error message.

The effect of *copy-field* actions in the action set is undefined due to race conditions, and therefore its implementation in the action set is discouraged (see 5.6).

## 7.2.6.9 Experimenter Action Structure

An Experimenter action uses the following structure and fields:

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8). The rest of the instruction body is experimenter defined, the whole action need to be padded to 64 bits.

#### 7.2.7 Controller Status Structure

The OpenFlow switch uses the controller status structure to inform the controller about the status of the control channel it maintains with each controller. This information is primarily useful in a multi-controller deployment.

The controller status structure always represents the switch's view of the status and looks like this:

```
/* Controller Status Property list. The Connection URI property is
    required; other properties are optional. */
    struct ofp_controller_status_prop_header properties[0];
};
OFP_ASSERT(sizeof(struct ofp_controller_status) == 16);
```

The short\_id is the identifier for the controller as set by that controller in a OFPT\_ROLE\_REQUEST message. If the switch has not requested an identifier, the short\_id should be set to OFPCID\_UNDEFINED. OFPCID\_UNDEFINED is 0.

The role is the role the controller currently has (see 6.3.6).

The reason indicates why the switch is sending the controller status. It is one of the following:

The channel\_status is the switch's view of the operational status of the control channel for the indicated controller. It takes its value from:

The properties field is a list of controller status properties, describing additional status information. The list of controller status property types that are currently defined are:

The OFPCSPT\_URI property is required and uses the following structure and fields:

The uri is the Connection URI of the controller and has the form *protocol:name-or-address:port*. For example: tls:192.168.34.23:6653. See 6.3.1 for more detail.

The optional OFPCSPT\_EXPERIMENTER property uses the following structure and fields:

```
/* Experimenter controller status property */
struct ofp_controller_status_prop_experimenter {
                     type;
                              /* OFPCSPT_EXPERIMENTER. */
    uint16_t
                     length; /* Length in bytes of this property. */
    uint16_t
    uint32_t
                     experimenter; /* Experimenter ID which takes the same
                                       form as in struct
                                       ofp_experimenter_header. */
    uint32_t
                                    /* Experimenter defined. */
                     exp_type;
    /* Followed by:
         - Exactly (length - 12) bytes containing the experimenter data, then
         - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
           bytes of all-zero bytes */
    uint32_t
                     experimenter_data[0];
};
OFP_ASSERT(sizeof(struct ofp_controller_status_prop_experimenter) == 12);
```

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8).

# 7.2.8 Experimenter Structure

Experimenter extensions provide a standard way for OpenFlow switches to offer additional functionality within the OpenFlow message type space. This is a staging area for features meant for future OpenFlow revisions. Many OpenFlow object types offer Experimenter extensions, such as basic messages (see 7.5.5), OXM matches (see 7.2.3.2), instructions (see 7.2.5), actions (see 7.2.6.9), queues (see 7.3.5.8), meters (see 7.3.4.5) and error (see 7.5.4.19).

A typical experimenter structure looks like this:

The actual Experimenter extension included in some object may not match exactly this structure due to various constraints.

The experimenter field is a 32-bit value that uniquely identifies the experimenter, the entity defining the experimenter extension. If the most significant byte is zero, the next three bytes are the experimenter's IEEE OUI. If the most significant byte is not zero, it is a value allocated by the Open Networking Foundation. If experimenter does not have (or wish to use) their OUI, they should contact the Open Networking Foundation to obtain a unique experimenter ID.

The exp\_type field is a 32-bit value present in some Experimenter extensions, it defines the experimenter type. This experimenter type is managed by the experimenter and can have any value and function the experimenter wishes.

The experimenter\_data field represent the rest of the body of the Experimenter extension, it is uninterpreted by standard OpenFlow processing and is arbitrarily defined by the corresponding experimenter. The length of that body must fit within the OpenFlow object and the OpenFlow object length must be properly set to accommodate this data. Some OpenFlow objects require the whole Experimenter extension to be padded to 64 bits.

The actual Experimenter extensions are outside the scope of this specification, they are always optional, and a switch is not required to support any Experimenter extension. If a switch does not understand an experimenter extension, it must reject the entire message and send an appropriate error message. The error message to use depend on the OpenFlow object (see 7.5.4). If a switch reject a specific Experimenter extension, the controller should no longer use that specific Experimenter extension in subsequent messages.

# 7.3 Controller-to-Switch Messages

#### 7.3.1 Handshake

The OFPT\_FEATURES\_REQUEST message is used by the controller to identify the switch and read its basic capabilities. Upon session establishment (see 6.3.2), the controller should send an OFPT\_FEATURES\_REQUEST message. This message does not contain a body beyond the OpenFlow header. The switch must respond with an OFPT\_FEATURES\_REPLY message:

```
uint8_t auxiliary_id;  /* Identify auxiliary connections */
uint8_t pad[2];  /* Align to 64-bits. */

/* Features. */
uint32_t capabilities;  /* Bitmap of support "ofp_capabilities". */
uint32_t reserved;
};

OFP_ASSERT(sizeof(struct ofp_switch_features) == 32);
```

The datapath\_id field uniquely identifies a datapath. The lower 48 bits are intended for the switch MAC address, while the top 16 bits are up to the implementer. An example use of the top 16 bits would be a VLAN ID to distinguish multiple virtual switch instances on a single physical switch. This field should be treated as an opaque bit string by controllers.

The n\_buffers field specifies the maximum number of packets the switch can buffer when sending packets to the controller using packet-in messages (see 6.1.2).

The n\_tables field describes the number of tables supported by the switch, each of which can have a different set of supported match fields, actions and number of entries. When the controller and switch first communicate, the controller will find out how many tables the switch supports from the Features Reply. If it wishes to understand the size, types, and order in which tables are consulted, the controller sends a OFPMP\_TABLE\_FEATURES multipart request (see 7.3.5.18). A switch must return these tables in the order the packets traverse the tables.

The auxiliary\_id field identifies the type of connection from the switch to the controller, the main connection has this field set to zero, an auxiliary connection has this field set to a non-zero value (see 6.3.7).

The capabilities field uses a combination of the following flags:

```
/* Capabilities supported by the datapath. */
enum ofp_capabilities {
   OFPC_FLOW_STATS
                        = 1 << 0, /* Flow statistics. */
    OFPC_TABLE_STATS
                        = 1 << 1, /* Table statistics. */
                        = 1 << 2, /* Port statistics. */
    OFPC_PORT_STATS
                        = 1 << 3, /* Group statistics. */
    OFPC_GROUP_STATS
                        = 1 << 5, /* Can reassemble IP fragments. */
    OFPC_IP_REASM
    OFPC_QUEUE_STATS
                        = 1 << 6, /* Queue statistics. */
    OFPC_PORT_BLOCKED
                       = 1 << 8, /* Switch will block looping ports. */
    OFPC_BUNDLES
                        = 1 << 9, /* Switch supports bundles. */
    <code>OFPC_FLOW_MONITORING</code> = 1 << 10, \ /* Switch supports flow monitoring. */
};
```

The OFPC\_PORT\_BLOCKED bit indicates that a switch protocol outside of OpenFlow, such as 802.1D Spanning Tree, will detect topology loops and block ports to prevent packet loops. If this bit is not set, in most cases the controller should implement a mechanism to prevent packet loops.

# 7.3.2 Switch Configuration

The controller is able to set and query configuration parameters in the switch with the OFPT\_SET\_CONFIG and OFPT\_GET\_CONFIG\_REQUEST messages, respectively. The switch responds to a configuration request with an OFPT\_GET\_CONFIG\_REPLY message; it does not reply to a request to set the configuration.

There is no body for OFPT\_GET\_CONFIG\_REQUEST beyond the OpenFlow header. The OFPT\_SET\_CONFIG and OFPT\_GET\_CONFIG\_REPLY use the following:

```
/* Switch configuration. */
struct ofp_switch_config {
   struct ofp header header;
   uint16_t flags;
                               /* Bitmap of OFPC_* flags. */
   uint16_t miss_send_len;
                               /* Max bytes of packet that datapath
                                  should send to the controller. See
                                  ofp_controller_max_len for valid values.
OFP_ASSERT(sizeof(struct ofp_switch_config) == 12);
The configuration flags include the following:
enum ofp_config_flags {
   /* Handling of IP fragments. */
   OFPC_FRAG_NORMAL = 0, /* No special handling for fragments. */
                      = 1 << 0, /* Drop fragments. */
   OFPC FRAG DROP
   OFPC_FRAG_REASM
                      = 1 << 1, /* Reassemble (only if OFPC_IP_REASM set). */
   OFPC_FRAG_MASK
                      = 3,
};
```

The OFPC\_FRAG\_\* flags indicate whether IP fragments should be treated normally, dropped, or reassembled. "Normal" handling of fragments means that an attempt should be made to pass the fragments through the OpenFlow tables. If any field is not present (e.g., the TCP/UDP ports didn't fit), then the packet should not match any entry that has that field set. Support for "normal" is mandatory, support for "drop" and "reasm" is optional.

The miss\_send\_len field defines the number of bytes of each packet sent to the controller by the OpenFlow pipeline when not using an output action to the OFPP\_CONTROLLER logical port, for example sending packets with invalid TTL if this message reason is enabled. If this field equals 0, the switch must send zero bytes of the packet in the ofp\_packet\_in message. If the value is set to OFPCML\_NO\_BUFFER the complete packet must be included in the message, and should not be buffered.

#### 7.3.3 Flow Table Configuration

Flow tables are numbered from 0 and can take any number until OFPTT\_MAX. OFPTT\_ALL is a reserved value.

Flow entries are modified in the flow table using the OFPT\_FLOW\_MOD request (see 7.3.4.2). Table statistics can be queried using the OFPMP\_TABLE\_STATS multipart requests (see 7.3.5.16). The controller can configure the dynamic state in a flow table with the OFPT\_TABLE\_MOD request (see 7.3.4.2). The flow table static features can be modified using the OFPMP\_TABLE\_FEATURES multipart request (see 7.3.5.18).

# 7.3.4 Modify State Messages

# 7.3.4.1 Modify Flow Table Message

The controller can configure the dynamic state in a flow table with the OFPT\_TABLE\_MOD request. The OFPT\_TABLE\_MOD use the following structure and fields:

The table\_id chooses the table to which the configuration change should be applied. If the table\_id is OFPTT\_ALL, the configuration is applied to all tables in the switch.

The **config** field is a bitmap that configures the behaviour of the table. The following values are defined for that field:

The flag OFPTC\_EVICTION control flow entry eviction in that flow table (see 6.5). If this flag is set, the switch can evict flow entries from that flow table. If this flag is unset, the switch cannot evict flow entries from that table. Flow entry eviction is optional and as a consequence a switch may not support setting this flag.

The flag OFPTC\_VACANCY\_EVENTS control vacancy events in that table (see 7.4.5). If this flag is set, the switch must generate vacancy events for that table. If this flag is unset, the switch must not generate those events. Parameters for vacancy events may be specified using the OFPTMPT\_VACANCY property (see below), if this property is not included in the table-mod message, previously set values of the parameters must be used.

The properties field is a list of table mod properties, describing dynamic parameters of table configuration.

The table mod property types currently defined are:

A property definition contains the property type, length, and any associated data:

The OFPTMPT\_EVICTION property usually cannot be modified using a OFP\_TABLE\_MOD request, because the eviction mechanism is switch defined, and this property is usually only used in a OFPMP\_TABLE\_DESC multipart reply to inform the controller about the eviction mechanism used. It uses the following structure and fields:

The flags field is a bitmap that defines the type of eviction the switch is implementing. The following flags:

If the flag OFPTMPEF\_IMPORTANCE is set, the eviction process will use the flow entry importance field (see 7.3.4.2) to perform eviction. If the flag OFPTMPEF\_IMPORTANCE is the only flag set, eviction will be performed strictly in order of importance, that is flow entry with lower importance will always be evicted before flow entry with higher importance. The eviction mechanism is switch defined, therefore it is not possible to predict in which order flow entries of same importance will get evicted.

If the flag OFPTMPEF\_LIFETIME is set, the eviction process will use the flow entry remaining lifetime, the shortest time to expiration (see 6.5), to perform eviction. If the flag OFPTMPEF\_LIFETIME is the only flag set, eviction will be performed stricly in order of remaining lifetime, and permanent flow entries are never removed.

If the flag OFPTMPEF\_OTHER is set, the eviction process will use other factors, such as internal constraints, to perform eviction. When this flag is set, the controller cannot predict in which order flow entries will get evicted. This flag may be combined with other flags to signify that, for example, eviction is mostly done by the switch according to importance or lifetime but not strictly.

The OFPTMPT\_VACANCY property specifies the parameters for vacancy events and uses the following structure and fields:

The fields vacancy\_down and vacancy\_up are the threshold for generating vacancy events that should be configured on this flow table, expressed as a percent.

When the remaining space in the flow table decreases to less than vacancy\_down, and if vacancy down events are enabled, a vacancy down event must be generated to the controller using the OFPT\_TABLE\_STATUS message type with reason OFPTR\_VACANCY\_DOWN (see 7.4.5). Further vacancy down events are disabled until a vacancy up event is generated.

When the remaining space in the flow table increases to more than vacancy\_up, and if vacancy up events are enabled, a vacancy up event must be generated to the controller using the OFPT\_TABLE\_STATUS message type with reason OFPTR\_VACANCY\_UP. Further vacancy up events are disabled until a vacancy down event is generated.

When vacancy events are enabled on the table using the OFPTC\_VACANCY\_EVENTS flag, either the vacancy up or vacancy down event is enabled. When enabling events, if the current vacancy is less than

vacancy\_up, vacancy up events must be enabled, and vacancy down events must be disabled. When enabling events, if the current vacancy is greater or equal to vacancy\_up, vacancy down events must be enabled, and vacancy up events must be disabled. When vacancy events are disabled on the table using the OFPTC VACANCY EVENTS flag, both vacancy up and vacancy down events must be disabled.

If in a OFP\_TABLE\_MOD message the value of vacancy\_down is greater than the value of vacancy\_up, the switch should reject the OFP\_TABLE\_MOD message and send an ofp\_error\_msg with OFPET\_BAD\_PROPERTY type and OFPBPC\_BAD\_VALUE code.

The vacancy field is only used when this property in included in a OFPMP\_TABLE\_DESC multipart reply or a OFPT\_TABLE\_STATUS message and represent the current vacancy of the table, expressed as a percent. In OFP\_TABLE\_MOD requests, this field must be set to 0.

The OFPTMPT\_EXPERIMENTER property uses the following structure and fields:

```
/* Experimenter table mod property */
struct ofp_table_mod_prop_experimenter {
                             /* OFPTMPT_EXPERIMENTER. */
   uint16_t
                    type;
                    length; /* Length in bytes of this property. */
   uint16_t
   uint32_t
                    experimenter; /* Experimenter ID which takes the same
                                       form as in struct
                                       ofp_experimenter_header. */
   uint32_t
                                    /* Experimenter defined. */
                     exp_type;
    /* Followed by:
        - Exactly (length - 12) bytes containing the experimenter data, then
        - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
    uint32_t
                    experimenter_data[0];
};
OFP_ASSERT(sizeof(struct ofp_table_mod_prop_experimenter) == 12);
```

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8).

#### 7.3.4.2 Modify Flow Entry Message

Modifications to a flow table from the controller are done with the OFPT FLOW MOD message:

```
/* Flow setup and teardown (controller -> datapath). */
struct ofp_flow_mod {
   struct ofp_header header;
   uint64_t cookie;
                                  /* Opaque controller-issued identifier. */
   uint64_t cookie_mask;
                                  /* Mask used to restrict the cookie bits
                                     that must match when the command is
                                     OFPFC_MODIFY* or OFPFC_DELETE*. A value
                                     of 0 indicates no restriction. */
    uint8_t table_id;
                                  /* ID of the table to put the flow in.
                                     For OFPFC_DELETE_* commands, OFPTT_ALL
                                     can also be used to delete matching
                                     flows from all tables. */
    uint8_t command;
                                  /* One of OFPFC_*. */
    uint16_t idle_timeout;
                                  /* Idle time before discarding (seconds). */
```

```
uint16_t hard_timeout;
                                  /* Max time before discarding (seconds). */
   uint16_t priority;
                                  /* Priority level of flow entry. */
    uint32_t buffer_id;
                                  /* Buffered packet to apply to, or
                                     OFP_NO_BUFFER.
                                     Not meaningful for OFPFC_DELETE*. */
   uint32_t out_port;
                                  /* For OFPFC_DELETE* commands, require
                                     matching entries to include this as an
                                     output port. A value of OFPP_ANY
                                     indicates no restriction. */
                                  /* For OFPFC_DELETE* commands, require
    uint32_t out_group;
                                     matching entries to include this as an
                                     output group. A value of OFPG_ANY
                                     indicates no restriction. */
   uint16_t flags;
                                  /* Bitmap of OFPFF_* flags. */
    uint16_t importance;
                                  /* Eviction precedence (optional). */
    struct ofp_match match;
                                  /* Fields to match. Variable size. */
    /* The variable size and padded match is always followed by instructions. */
    //struct ofp_instruction_header instructions[0];
                          /* Instruction set - 0 or more. The length
                                     of the instruction set is inferred from
                                     the length field in the header. */
};
OFP_ASSERT(sizeof(struct ofp_flow_mod) == 56);
```

The cookie field is an opaque data value chosen by the controller. This value appears in flow removed messages (see 7.4.2) and flow description multipart messages (see 7.3.5.2), and can also be used to filter flow statistics, flow modification and flow deletion (see 6.4). It is not used by the packet processing pipeline, and thus does not need to reside in hardware. The value -1 (0xfffffffffffff) is reserved and must not be used. When a flow entry is inserted in a table through an OFPFC\_ADD message, its cookie field is set to the provided value. When a flow entry is modified (OFPFC\_MODIFY or OFPFC\_MODIFY\_STRICT messages), its cookie field is unchanged.

If the cookie\_mask field is non-zero, it is used with the cookie field to restrict flow matching while modifying or deleting flow entries. This field is ignored by OFPFC\_ADD messages. The cookie\_mask field's behavior is explained in Section 6.4.

The table\_id field specifies the table into which the flow entry should be inserted, modified or deleted. Table 0 signifies the first table in the pipeline. The use of OFPTT\_ALL is only valid for delete requests.

The command field must be one of the following:

The differences between OFPFC\_MODIFY and OFPFC\_MODIFY\_STRICT, and between OFPFC\_DELETE and OFPFC\_DELETE\_STRICT are explained in Section 6.4.

The idle\_timeout and hard\_timeout fields control how quickly flow entries expire (see 6.5). When a flow entry is inserted in a table, its idle\_timeout and hard\_timeout fields are set with the values from the message. When a flow entry is modified (OFPFC\_MODIFY or OFPFC\_MODIFY\_STRICT messages), the idle\_timeout and hard\_timeout fields are ignored.

The flow entry timeout values are used by the switch flow expiry mechanism. If the idle\_timeout is set and the hard\_timeout is zero, the entry must expire after idle\_timeout seconds with no received traffic. If the idle\_timeout is zero and the hard\_timeout is set, the entry must expire in hard\_timeout seconds regardless of whether or not packets are hitting the entry. If both idle\_timeout and hard\_timeout are set, the flow entry will timeout after idle\_timeout seconds with no traffic, or hard\_timeout seconds, whichever comes first. If both idle\_timeout and hard\_timeout are zero, the entry is considered permanent and will never time out. It can still be removed with a flow\_mod message of type OFPFC\_DELETE. The accuracy of the flow expiry process is not defined by the specification and is switch implementation dependant.

The priority field indicates the priority of the flow entry within the specified flow table. Higher numbers indicate higher priorities when matching packets (see 5.3). This field is used only for OFPFC\_ADD messages when matching and adding flow entries, and for OFPFC\_MODIFY\_STRICT or OFPFC\_DELETE\_STRICT messages when matching flow entries. This field is not used for OFPFC\_MODIFY or OFPFC\_DELETE (non-strict) messages.

The buffer\_id refers to a packet buffered at the switch and sent to the controller by a packet-in message. If no buffered packet is associated with the flow mod, it must be set to OFP\_NO\_BUFFER. A flow mod that includes a valid buffer\_id removes the corresponding packet from the buffer and processes it through the entire OpenFlow pipeline after the flow is inserted, starting at the first flow table. This is effectively equivalent to sending a two-message sequence of a flow mod and a packet-out forwarding to the OFPP\_TABLE logical port (see 7.3.6), with the requirement that the switch must fully process the flow mod before the packet out. These semantics apply regardless of the table to which the flow mod refers, or the instructions contained in the flow mod. This field is ignored by OFPFC\_DELETE and OFPFC\_DELETE\_STRICT flow mod messages.

The out\_port and out\_group fields optionally filter the scope of OFPFC\_DELETE and OFPFC\_DELETE\_STRICT messages by output port and group. If either out\_port or out\_group contains a value other than OFPP\_ANY or OFPG\_ANY respectively, it introduces a constraint when matching. This constraint is that the flow entry must contain an output action directed at that port or group. Other constraints such as ofp\_match structs and priorities are still used; this is purely an additional constraint. Note that to disable output filtering, both out\_port and out\_group must be set to OFPP\_ANY and OFPG\_ANY respectively. These fields are ignored by OFPFC\_ADD, OFPFC\_MODIFY or OFPFC\_MODIFY\_STRICT messages.

The flags field may include a combination of the following flags:

When the OFPFF\_SEND\_FLOW\_REM flag is set, the switch must send a flow removed message when the flow entry expires or is deleted.

When the OFPFF\_CHECK\_OVERLAP flag is set, the switch must check that there are no conflicting entries with the same priority prior to inserting it in the flow table (see 6.4). If there is one, the flow mod fails and an error message is returned (see 7.5.4.6).

When the OFPFF\_RESET\_COUNTS flag is set, the switch must clear the counters (byte and packet count) of the matching flow entries, if this flag is unset the counters are preserved.

When the OFPFF\_NO\_PKT\_COUNTS flag is set, the switch does not need to keep track of the flow packet count. When the OFPFF\_NO\_BYT\_COUNTS flag is set, the switch does not need to keep track of the flow byte count. Setting those flags may decrease the processing load on some OpenFlow switches, however those counters may not be available in flow statistics and flow removed messages for this flow entry. A switch is not required to honor those flags and may keep track of a flow count and return it despite the corresponding flag being set. If a switch does not keep track of a flow count, the corresponding counter is not available and must be set to the maximum field value (see 5.9).

When a flow entry is inserted in a table, its flags field is set with the values from the message. When a flow entry is matched and modified (OFPFC\_MODIFY or OFPFC\_MODIFY\_STRICT messages), the flags of the flow entry is not changed, only OFPFF\_RESET\_COUNTS is used and other flags are ignored.

The match field contains the match structure and set of match fields defining how the flow entry matches packets (see 7.2.3). The combination of match field and priority field uniquely identifies a flow entry in the table (see 5.2).

The importance field is the importance of the flow entry. This field may be optionally used by the flow entry eviction mechanism (see 6.5).

The instructions field contains the instruction set for the flow entry when adding or modifying entries (see 7.2.5). If the instruction set is not valid or supported, the switch must generate an error (see 7.5.4.4).

# 7.3.4.3 Modify Group Entry Message

Modifications to the group table from the controller are done with the OFPT\_GROUP\_MOD message:

```
/* Group setup and teardown (controller -> datapath). */
struct ofp_group_mod {
   struct ofp_header header;
   uint16_t command;
                                 /* One of OFPGC_*. */
   uint8_t type;
                                 /* One of OFPGT_*. */
   uint8 t pad;
                                 /* Pad to 64 bits. */
   uint32_t group_id;
                                /* Group identifier. */
   uint16_t bucket_array_len;
                               /* Length of action buckets data. */
   uint8_t pad2[2];
                                 /* Pad to 64 bits. */
   uint32_t command_bucket_id; /* Bucket Id used as part of
                                    OFPGC_INSERT_BUCKET and OFPGC_REMOVE_BUCKET
                                    commands execution.*/
   /* Followed by:
       - Exactly 'bucket_array_len' bytes containing an array of
          struct ofp_bucket.
```

The semantics of the type and group fields are explained in Section 6.7.

The command field must be one of the following:

The command OFPGC\_ADD creates a new group based on the content of the request (and returns an error if a group with the same <code>group\_id</code> already exists). The command OFPGC\_MODIFY replaces the definition of an existing group with the content of the request. The command OFPGC\_DELETE destroys the group specified by <code>group\_id</code>, or all groups if <code>group\_id</code> is OFPG\_ALL. The command OFPGC\_INSERT\_BUCKET adds buckets to an existing group. The command OFPGC\_REMOVE\_BUCKET removes buckets from an existing group.

The type field specifies how the group behaves and which group buckets will be used to process packets (see 5.10.1), it must be one of the following values:

The group\_id field uniquely identifies a group within a switch, a group can have any Group ID lower than OFPG\_MAX as long as it is unique on the switch. The following special group identifiers are defined:

```
/* Group numbering. Groups can use any number up to OFPG_MAX. */
enum ofp_group {
   /* Last usable group number. */
   OFPG_MAX = Oxfffffff00,

   /* Fake groups. */
```

```
OFPG_ALL = Oxfffffffc, /* Represents all groups for group delete commands. */
OFPG_ANY = Oxffffffff /* Special wildcard: no group specified. */
};
```

The bucket\_array\_len field is the size in bytes of the array of buckets in the buckets field.

The command\_bucket\_id field is either the Bucket ID of one of the buckets already existing in the group, or one of the following special bucket identifiers:

The interpretation of the command\_bucket\_id field and which Bucket IDs are valid for that field depends on the command field. For OFPGC\_INSERT\_BUCKET, it defines the place in the bucket list to insert the new buckets. For OFPGC\_REMOVE\_BUCKET, it defines the buckets to be removed. The commands OFPGC\_ADD, OFPGC\_MODIFY and OFPGC\_DELETE don't use the command\_bucket\_id field, for those commands it must be set to OFPG\_BUCKET\_ALL.

The buckets field is a list of buckets. Group buckets are described in the next section (see 7.3.4.3.1).

The properties field is a list of group properties. Group properties are described in a following section (see 7.3.4.3.2).

#### **7.3.4.3.1** Group Buckets

The buckets field in the OFPT\_GROUP\_MOD message is a list of buckets. An *Indirect* group must contain exactly one bucket (see 5.10.1), therefore the buckets field must contain a single bucket and any command that would make such a group have multiple buckets must return an error (see 7.5.4.7). Other group types may have multiple buckets in the buckets field. For *Fast Failover* group, the bucket order does define the bucket priorities (see 5.10.1), and the bucket order can be changed by modifying the group (for example using a OFPT\_GROUP\_MOD message with command OFPGC\_MODIFY).

Group buckets use the following structure:

The action\_array\_len field is the size in bytes of the set of actions in the actions field.

The bucket\_id field uniquely identifies an action bucket of a group within a switch. Each bucket of the group must have an unique Bucket ID; if a group mod would make the group have a duplicate Bucket ID, the switch must refuse the group mod and send a *Bucket Exist* error message (see 7.5.4.7). The bucket\_id field must be lower than OFPG\_BUCKET\_MAX (it can not be one of the special bucket values).

The actions field is the set of actions associated with the bucket. When the bucket is selected for a packet, its actions are applied to the packet as an action set (see 5.6).

The properties field is a list of group bucket properties.

The list of group bucket property types that are currently defined are:

A property definition contains the property type, length, and any associated data:

The OFPGBPT\_WEIGHT property uses the following structure and fields:

```
uint16_t weight; /* Relative weight of bucket. */
uint8_t pad[2]; /* Pad to 64 bits. */
};

OFP_ASSERT(sizeof(struct ofp_group_bucket_prop_weight) == 8);
```

The weight field is only defined for select groups, and its support is optional. For other group types, this property must be omitted. In select groups, the weight field is used to support unequal load sharing. If the switch does not support unequal load sharing, this field must be set to 1. The bucket's share of the traffic processed by the group is defined by the individual bucket's weight divided by the sum of the bucket weights in the group. If its weight is set to zero, the bucket is not used by the select group. When a port goes down, the change in traffic distribution is undefined. The precision by which a switch's packet distribution should match bucket weights is undefined.

The OFPGBPT\_WATCH\_PORT and OFPGBPT\_WATCH\_GROUP properties use the following structure and fields:

The watch field is respectively the port number or group identifier that is being watched by the bucket.

The OFPGBPT\_WATCH\_PORT and OFPGBPT\_WATCH\_GROUP properties are only required for fast failover groups, and may be optionally implemented for other group types. These properties indicate the port and/or group whose liveness controls whether this bucket is a candidate for forwarding (see 6.7). If watch\_port is OFPP\_ANY, no port is being watched. If watch\_group is OFPG\_ANY, no group is being watched. For fast failover groups, the first bucket defined is the highest-priority bucket, and only the highest-priority live bucket is used (see 5.10.1).

The OFPGBPT\_EXPERIMENTER property uses the following structure and fields:

```
/* Experimenter group bucket property */
struct ofp_group_bucket_prop_experimenter {
                                  /* OFPGBPT_EXPERIMENTER. */
   uint16_t
                    type;
   uint16_t
                    length;
                                  /* Length in bytes of this property. */
    uint32_t
                     experimenter; /* Experimenter ID which takes the same
                                       form as in struct
                                       ofp_experimenter_header. */
   uint32_t
                                    /* Experimenter defined. */
                     exp_type;
    /* Followed by:
       - Exactly (length - 12) bytes containing the experimenter data, then
         - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
    uint32_t
                    experimenter_data[0];
};
OFP_ASSERT(sizeof(struct ofp_group_bucket_prop_experimenter) == 12);
```

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8).

### 7.3.4.3.2 Group Properties

The properties field in the OFPT\_GROUP\_MOD message is a list of group properties.

The list of group property types that are currently defined are:

```
/* Group property types. */
enum ofp_group_prop_type {
    OFPGPT_EXPERIMENTER = OxFFFF, /* Experimenter defined. */
};
```

A property definition contains the property type, length, and any associated data:

The OFPGPT\_EXPERIMENTER property uses the following structure and fields:

```
/* Experimenter group property */
struct ofp_group_prop_experimenter {
                  type; /* OFPGPT_EXPERIMENTER. */
   uint16_t
                                 /* Length in bytes of this property. */
   uint16_t
                    length;
   uint32_t
                  experimenter; /* Experimenter ID which takes the same
                                     form as in struct
                                      ofp_experimenter_header. */
   uint32_t
                                   /* Experimenter defined. */
                    exp_type;
   /* Followed by:
        - Exactly (length - 12) bytes containing the experimenter data, then
        - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
   uint32_t
                    experimenter_data[0];
};
OFP_ASSERT(sizeof(struct ofp_group_prop_experimenter) == 12);
```

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8).

# 7.3.4.4 Port Modification Message

The controller uses the OFPT\_PORT\_MOD message to modify the behavior of the port:

```
/* Modify behavior of the physical port */
struct ofp_port_mod {
   struct ofp_header header;
   uint32_t port_no;
   uint8_t pad[4];
   uint8_t hw_addr[OFP_ETH_ALEN]; /* The hardware address is not
                                     configurable. This is used to
                                     sanity-check the request, so it must
                                     be the same as returned in an
                                     ofp_port struct. */
   uint8_t pad2[2];
                         /* Pad to 64 bits. */
    uint32_t config;
                          /* Bitmap of OFPPC_* flags. */
                          /* Bitmap of OFPPC_* flags to be changed. */
   uint32_t mask;
    /* Port mod property list - 0 or more properties */
    struct ofp_port_mod_prop_header properties[0];
};
OFP_ASSERT(sizeof(struct ofp_port_mod) == 32);
```

The config field describes port administrative settings (see 7.2.1).

The mask field is used to select bits in the config field to change.

The properties field is a list of port description properties, enabling to configure additional properties of the port. All port properties do not need to be included in the OFPT\_PORT\_MOD message, properties that are omitted are unchanged.

The list of port description property types that are currently defined are:

A property definition contains the property type, length, and any associated data:

The OFPPMPT\_ETHERNET property uses the following structure and fields:

The advertise field describe Ethernet features advertised on the link (7.2.1). It has no mask; all port features change together.

The OFPPMPT\_OPTICAL property uses the following structure and fields:

```
struct ofp_port_mod_prop_optical {
                         /* OFPPMPT_OPTICAL. */
   uint16_t type;
   uint16_t
              length; /* Length in bytes of this property. */
              configure; /* Bitmap of OFPOPF_*. */
   uint32_t
              freq_lmda; /* The "center" frequency */
   uint32 t
   int32_t
              fl_offset; /* signed frequency offset */
   uint32_t
                grid_span; /* The size of the grid for this port */
                          /* tx power setting */
   uint32_t
                tx_pwr;
OFP_ASSERT(sizeof(struct ofp_port_mod_prop_optical) == 24);
```

The configure field describes optical features to change for this port. Any of OFPOPF\_\* may be set. Frequency is specified in MHz, wavelength (lambda) as nm \* 100. The OFPOPF\_USE\_FREQ must match the advertised port feature. The tx\_pwr is dBm \* 10.

The tuned frequency is the sum of freq\_lmda and fl\_offset. This is for convenience of the software, since some tuning options, including Flex Grid, may be based upon a center frequency and an offset. The "center" frequency is often used for passive filters, again making this convenient for the software. The grid\_span is the amount of bandwidth consumed by this port, useful for Flex Grid as well as other tuning information.

The OFPPMPT EXPERIMENTER property uses the following structure and fields:

```
/* Experimenter port mod property. */
struct ofp_port_mod_prop_experimenter {
                           /* OFPPMPT_EXPERIMENTER. */
   uint16_t
                   type;
                    length; /* Length in bytes of this property. */
   uint16_t
   uint32_t
                    experimenter; /* Experimenter ID which takes the same
                                      form as in struct
                                      ofp_experimenter_header. */
   uint32_t
                                   /* Experimenter defined. */
                    exp_type;
   /* Followed by:
        - Exactly (length - 12) bytes containing the experimenter data, then
        - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
   uint32_t
                    experimenter_data[0];
};
OFP_ASSERT(sizeof(struct ofp_port_mod_prop_experimenter) == 12);
```

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8).

#### 7.3.4.5 Meter Modification Message

Modifications to a meter from the controller are done with the OFPT METER MOD message:

```
/* Meter configuration. OFPT_METER_MOD. */
struct ofp_meter_mod {
   struct ofp_header header;
   uint16 t
                                       /* One of OFPMC_*. */
                       command;
   uint16_t
                                      /* Bitmap of OFPMF_* flags. */
                      flags;
                                       /* Meter instance. */
   uint32 t
                      meter id;
   struct ofp_meter_band_header bands[0]; /* The band list length is
                                          inferred from the length field
                                          in the header. */
};
OFP_ASSERT(sizeof(struct ofp_meter_mod) == 16);
```

The meter\_id field uniquely identifies a meter within a switch. Meters are defined starting with meter\_id=1 up to the maximum number of meters that the switch can support. The OpenFlow switch protocol also defines some additional virtual meters that can not be associated with flows:

```
/* Meter numbering. Flow meters can use any number up to OFPM_MAX. */
enum ofp_meter {
    /* Last usable meter. */
    OFPM_MAX = Oxfffff0000,

    /* Virtual meters. */
    OFPM_SLOWPATH = Oxffffffffd, /* Meter for slow datapath. */
    OFPM_CONTROLLER = Oxfffffffe, /* Meter for controller connection. */
    OFPM_ALL = Oxffffffff, /* Represents all meters for stat requests commands. */
};
```

Virtual meters are provided to support existing implementations of OpenFlow. New implementations are encouraged to use regular per-flow meters (see 5.11) or priority queues (see 7.3.5.8) instead.

- OFPM\_CONTROLLER: Virtual meter controlling all packets sent to the controllers via *Packet-in* messages, either using the **CONTROLLER** reserved port or in other processing (see 6.1.2). Can be used to limit the amount of traffic sent to the controllers.
- OFPM\_SLOWPATH: Virtual meter controlling all packets processed by the slow datapath of the switch. Many switch implementations have a fast and slow datapath, for example a hardware switch may have a slow software datapath, or a software switch may have a slow userspace datapath.

The command field must be one of the following:

The flags field may include a combination of following flags:

The bands field is a list of rate bands. It can contain any number of bands, and each band type can be repeated when it makes sense. Only a single band is used at a time, if the current rate of packets exceeds the rate of multiple bands, the band with the highest configured rate is used.

All the rate bands are defined using the same common header:

The rate field indicates the rate value above which the corresponding band may apply to packets (see 5.11.1). The rate value is in kilobits per second, unless the flags field includes OFPMF\_PKTPS, in which case the rate is in packets per second.

The burst\_size field is used only if the flags field includes OFPMF\_BURST. It defines the granularity of the meter band, for all packet or byte bursts which length is greater than burst value, the meter rate will always be strictly enforced. The burst value is in kilobits, unless the flags field includes OFPMF\_PKTPS, in which case the burst value is in packets.

The type field must be one of the following:

An OpenFlow switch may not support all band types, and may not allow the use of all its supported band types on all meters, i.e. some meters may be specialised.

The band OFPMBT\_DROP defines a simple rate limiter that drops packets that exceed the band rate value, and uses the following structure:

```
/* OFPMBT_DROP band - drop packets */
struct ofp_meter_band_drop {
                           /* OFPMBT_DROP. */
   uint16_t
             type;
   uint16_t
                  len;
                           /* Length is 16. */
                 rate; /* Rate for dropping packets. */
   uint32_t
   uint32_t
                 burst_size; /* Size of bursts. */
                  pad[4];
   uint8_t
};
OFP_ASSERT(sizeof(struct ofp_meter_band_drop) == 16);
```

The band OFPMBT\_DSCP\_REMARK defines a simple DiffServ policer that remarks the drop precedence of the DSCP field in the IP header of the packets that exceed the band rate value, and uses the following structure:

```
/* OFPMBT_DSCP_REMARK band - Remark DSCP in the IP header */
struct ofp_meter_band_dscp_remark {
   uint16_t type; /* OFPMBT_DSCP_REMARK. */
   uint16_t
                   len;
                           /* Length is 16. */
   uint32_t
                  rate;
                          /* Rate for remarking packets. */
                  burst_size; /* Size of bursts. */
   uint32_t
   uint8_t
                  prec_level; /* Number of drop precedence level to add. */
   uint8_t
                   pad[3];
};
OFP_ASSERT(sizeof(struct ofp_meter_band_dscp_remark) == 16);
```

The prec\_level field indicates by which amount the drop precedence of the packet should be increased if the band is exceeded. This band increases the encoded drop precedence by this amount, not the raw DSCP value; it always results in a valid DSCP value, and DSCP values that do not encode a drop precedence are not modified.

The band OFPMBT\_EXPERIMENTER is experimenter defined and uses the following structure:

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8). The rest of the band body is experimenter defined.

# 7.3.5 Multipart Messages

Multipart messages are used to encode requests or replies that potentially carry a large amount of data and would not always fit in a single OpenFlow message, which is limited to 64KB. The request or reply is encoded as a sequence of multipart messages on the same connection with a specific multipart type, and re-assembled by the receiver. Each sequence of multipart messages carries a single multipart request or reply. Multipart messages are primarily used to request statistics or state information from the switch.

The request is carried in one or more OFPT\_MULTIPART\_REQUEST messages:

```
struct ofp_multipart_request {
   struct ofp_header header;
   uint16_t type;
                               /* One of the OFPMP_* constants. */
                               /* OFPMPF_REQ_* flags. */
   uint16_t flags;
   uint8_t pad[4];
                               /* Body of the request. 0 or more bytes. */
   uint8_t body[0];
OFP_ASSERT(sizeof(struct ofp_multipart_request) == 16);
The switch responds with one or more OFPT MULTIPART REPLY messages:
struct ofp_multipart_reply {
   struct ofp_header header;
   uint16_t type;
                               /* One of the OFPMP_* constants. */
   uint16_t flags;
                               /* OFPMPF_REPLY_* flags. */
   uint8_t pad[4];
   uint8_t body[0];
                               /* Body of the reply. 0 or more bytes. */
```

The body field contains one segment of the request or reply. Every multipart request or reply is defined either as a single structure or as an array of 0 or more structures of the same type. If the multipart request or reply is defined as a single structure, it must use a single multipart message and the whole request or reply must be included in the body. If the multipart request or reply is defined as an array of structures, the body field must contain an integral number of objects, and no object can be split across two messages. To ease implementation, a multipart request or reply defined as an array may use messages with no additional entries (i.e. an empty body) at any point of the multipart sequence.

The flags field controls the segmentation/reassembly process. In a multipart request message, it may have the following values:

```
enum ofp_multipart_request_flags {
     OFPMPF_REQ_MORE = 1 << 0 /* More requests to follow. */
};</pre>
```

OFP\_ASSERT(sizeof(struct ofp\_multipart\_reply) == 16);

In a multipart reply message, it may have the following values:

```
enum ofp_multipart_reply_flags {
     OFPMPF_REPLY_MORE = 1 << 0 /* More replies to follow. */
};</pre>
```

The OFPMPF\_REQ\_MORE bit and the OFPMPF\_REPLY\_MORE bit indicate that more requests/replies will follow the current one. If OFPMPF\_REQ\_MORE or OFPMPF\_REPLY\_MORE is set in a multipart message, then another multipart message of the same multipart sequence must always follow that message. A request or reply that spans multiple messages (has one or more messages with the *more* flag set), must use the same multipart type and transaction id (xid) for all messages in the message sequence.

Messages from a multipart request or reply may be interleaved with other OpenFlow message types, including other multipart requests or replies, but must have a distinct transaction ID on the connection if multiple unanswered multipart requests or replies are in flight simultaneously. Transaction ids of replies must always match the request that prompted them.

If a multipart request spans multiple messages and grows to a size that the switch is unable to buffer, the switch must respond with an error message of type OFPET\_BAD\_REQUEST and code OFPBRC\_MULTIPART\_BUFFER\_OVERFLOW. If a multipart request contains a type that is not supported, the switch must respond with an error message of type OFPET\_BAD\_REQUEST and code OFPBRC\_BAD\_MULTIPART. If the switch receives a multipart message with the same xid as a multipart sequence received earlier on the same connection which is not terminated (did not receive a messages without the *more* flag set), and with a different multipart type, the switch must respond with an error message of type OFPET\_BAD\_REQUEST and code OFPBRC\_BAD\_MULTIPART. If a multipart request sequence contains more than one multipart request or other data beyond a single request, the switch must respond with an error message of type OFPET\_BAD\_REQUEST and code OFPBRC\_BAD\_LEN.

If a switch receives a multipart request message sequence that does not include a message with OFPMPF\_REQ\_MORE flag set to zero, after a switch defined amount of time greater than 100 milliseconds from the last message, the switch must discard the incomplete multipart request, and may generate an error messsage of type OFPET\_BAD\_REQUEST and code OFPBRC\_MULTIPART\_REQUEST\_TIMEOUT to the controller. If a controller receives a multipart reply message sequence that does not include a message with OFPMPF\_REPLY\_MORE flag set to zero, after a controller defined amount of time greater than 1 second from the last message, the controller must discard the incomplete multipart reply, and may generate an error messsage of type OFPET\_BAD\_REQUEST and code OFPBRC\_MULTIPART\_REPLY\_TIMEOUT to the switch. The controller may retry the failed switch operation as needed as a new multipart request.

In all types of multipart replies containing statistics, if a specific numeric counter is not available in the switch, if the counter is described using OXS (see 7.2.4.2), it must be omitted, otherwise its value must be set to the maximum field value (the unsigned equivalent of -1). Counters are unsigned and wrap around with no overflow indicator.

In both the request and response, the type field specifies the kind of information being passed and determines how the body field is interpreted:

```
enum ofp_multipart_type {
    /* Description of this OpenFlow switch.
    * The request body is empty.
    * The reply body is struct ofp_desc. */
    OFPMP_DESC = 0,
```

```
/* Individual flow descriptions and statistics.
* The request body is struct ofp_flow_stats_request.
* The reply body is an array of struct ofp_flow_desc. */
OFPMP_FLOW_DESC = 1,
/* Aggregate flow statistics.
* The request body is struct ofp_aggregate_stats_request.
* The reply body is struct ofp_aggregate_stats_reply. */
OFPMP_AGGREGATE_STATS = 2,
/* Flow table statistics.
* The request body is empty.
 * The reply body is an array of struct ofp_table_stats. */
OFPMP_TABLE_STATS = 3,
/* Port statistics.
* The request body is struct ofp_port_multipart_request.
* The reply body is an array of struct ofp_port_stats. */
OFPMP_PORT_STATS = 4,
/* Queue statistics for a port
* The request body is struct ofp_queue_multipart_request.
* The reply body is an array of struct ofp_queue_stats */
OFPMP_QUEUE_STATS = 5,
/* Group counter statistics.
* The request body is struct ofp_group_multipart_request.
* The reply is an array of struct ofp_group_stats. */
OFPMP\_GROUP\_STATS = 6,
/* Group description.
* The request body is struct ofp_group_multipart_request.
* The reply body is an array of struct ofp_group_desc. */
OFPMP\_GROUP\_DESC = 7,
/* Group features.
* The request body is empty.
* The reply body is struct ofp_group_features. */
OFPMP_GROUP_FEATURES = 8,
/* Meter statistics.
* The request body is struct ofp_meter_multipart_request.
* The reply body is an array of struct ofp_meter_stats. */
OFPMP\_METER\_STATS = 9,
/* Meter configuration.
* The request body is struct ofp_meter_multipart_request.
* The reply body is an array of struct ofp_meter_desc. */
OFPMP_METER_DESC = 10,
/* Meter features.
* The request body is empty.
* The reply body is struct ofp_meter_features. */
OFPMP_METER_FEATURES = 11,
/* Table features.
* The request body is either empty or contains an array of
```

```
* struct ofp_table_features containing the controller's
    * desired view of the switch. If the switch is unable to
    * The reply body is an array of struct ofp_table_features. */
   OFPMP_TABLE_FEATURES = 12,
   /* Port description.
    * The request body is struct ofp_port_multipart_request.
    * The reply body is an array of struct ofp_port. */
   OFPMP_PORT_DESC = 13,
   /* Table description.
    * The request body is empty.
    * The reply body is an array of struct ofp_table_desc. */
   OFPMP_TABLE_DESC = 14,
   /* Queue description.
    * The request body is struct ofp_queue_multipart_request.
    * The reply body is an array of struct ofp_queue_desc. */
   OFPMP_QUEUE_DESC = 15,
   /* Flow monitors. Reply may be an asynchronous message.
    * The request body is struct ofp_flow_monitor_request.
    * The reply body is an array of struct ofp_flow_update_header. */
   OFPMP_FLOW_MONITOR = 16,
   /* Individual flow statistics (without description).
    * The request body is struct ofp_flow_stats_request.
    * The reply body is an array of struct ofp_flow_stats. */
   OFPMP_FLOW_STATS = 17,
   /* Controller status.
    * The request body is empty.
    * The reply body is an array of struct ofp_controller_status. */
   OFPMP_CONTROLLER_STATUS = 18,
   /* Bundle features.
   * The request body is ofp_bundle_features_request.
   * The reply body is struct ofp_bundle_features. */
   OFPMP_BUNDLE_FEATURES = 19,
   /* Experimenter extension.
    * struct ofp_experimenter_multipart_header.
    * The request and reply bodies are otherwise experimenter-defined. */
   OFPMP_EXPERIMENTER = Oxffff
};
```

#### 7.3.5.1 Description

Information about the switch manufacturer, hardware revision, software revision, serial number, and a description field is available from the OFPMP\_DESC multipart request type:

```
/* Body of reply to OFPMP_DESC request. Each entry is a NULL-terminated
 * ASCII string. */
```

Each entry is ASCII formatted and padded on the right with null bytes (\0). DESC\_STR\_LEN is 256 and SERIAL\_NUM\_LEN is 32. The dp\_desc field is a free-form string to describe the datapath for debugging purposes, e.g., "switch3 in room 3120". As such, it is not guaranteed to be unique and should not be used as the primary identifier for the datapath—use the datapath\_id field from the switch features instead (see 7.3.1).

# 7.3.5.2 Individual Flow Descriptions

Information about individual flow entries is requested with the OFPMP\_FLOW\_DESC multipart request type:

```
/* Body for ofp_multipart_request of type OFPMP_FLOW_DESC & OFPMP_FLOW_STATS. */
struct ofp_flow_stats_request {
                        /* ID of table to read (from ofp_table_desc),
   uint8_t table_id;
                                OFPTT_ALL for all tables. */
   uint8_t pad[3];
                             /* Align to 32 bits. */
   uint32_t out_port;
                             /* Require matching entries to include this
                                as an output port. A value of OFPP_ANY
                                indicates no restriction. */
                             /* Require matching entries to include this
   uint32_t out_group;
                                as an output group. A value of OFPG_ANY
                                indicates no restriction. */
   uint8_t pad2[4];
                             /* Align to 64 bits. */
   uint64_t cookie;
                             /* Require matching entries to contain this
                                cookie value */
   uint64_t cookie_mask;
                             /* Mask used to restrict the cookie bits that
                                must match. A value of 0 indicates
                                no restriction. */
   struct ofp_match match;
                             /* Fields to match. Variable size. */
};
OFP_ASSERT(sizeof(struct ofp_flow_stats_request) == 40);
```

The match field contains a description of the flow entries that should be matched and may contain wildcarded and masked fields. This field's matching behavior is described in Section 6.4.

The table\_id field indicates the index of a single table to read, or OFPTT\_ALL for all tables.

The out\_port and out\_group fields optionally filter by output port and group. If either out\_port or out\_group contain a value other than OFPP\_ANY and OFPG\_ANY respectively, it introduces a constraint when matching. This constraint is that the flow entry must contain an output action directed at that port or group. Other constraints such as match field are still used; this is purely an additional

constraint. Note that to disable output filtering, both out\_port and out\_group must be set to OFPP\_ANY and OFPG\_ANY respectively.

The usage of the cookie and cookie\_mask fields is defined in Section 6.4.

The body of the reply to a OFPMP\_FLOW\_DESC multipart request consists of an array of the following:

```
/* Body of reply to OFPMP_FLOW_DESC request. */
  struct ofp flow desc {
                      /* ID of table flow came from. */
   uint8_t pad;
                      /* Priority of the entry. */
   uint16_t priority;
   uint16_t idle_timeout;  /* Number of seconds idle before expiration. */
   uint16_t hard_timeout;  /* Number of seconds before expiration. */
  struct ofp_match match; /* Description of fields. Variable size. */
   //struct ofp_stats stats; /* Statistics list. Variable size. */
   //struct ofp_instruction_header instructions[0];
                        /* Instruction set - 0 or more. */
};
OFP_ASSERT(sizeof(struct ofp_flow_desc) == 32);
```

The fields consist of those provided in the flow\_mod that created the flow entry (see 7.3.4.2), plus the table\_id into which the entry was inserted.

The stats field contains a list of OXS fields (see 7.2.4.2). The field OXS\_OF\_DURATION is mandatory and tracks of how long the flow entry has been installed in the switch. The fields OXS\_OF\_PACKET\_COUNT and OXS\_OF\_BYTE\_COUNT are optional and count all packets processed by the flow entry.

#### 7.3.5.3 Individual Flow Statistics

Statistics about individual flow entries can also be requested with the OFPMP\_FLOW\_STATS multipart request type:

```
/* Body for ofp_multipart_request of type OFPMP_FLOW_DESC & OFPMP_FLOW_STATS. */
struct ofp_flow_stats_request {
   uint8_t table_id; /* ID of table to read (from ofp_table_desc),
                                OFPTT_ALL for all tables. */
   uint8_t pad[3];
                            /* Align to 32 bits. */
   uint32_t out_port;
                             /* Require matching entries to include this
                                as an output port. A value of OFPP_ANY
                                indicates no restriction. */
   uint32_t out_group;
                             /* Require matching entries to include this
                                as an output group. A value of OFPG_ANY
                                indicates no restriction. */
   uint8_t pad2[4];
                             /* Align to 64 bits. */
   uint64_t cookie;
                            /* Require matching entries to contain this
                                cookie value */
   uint64_t cookie_mask;
                            /* Mask used to restrict the cookie bits that
```

The fields in this message have the same meanings as in the individual flow desc request type (OFPMP FLOW DESC - see 7.3.5.2).

The body of the reply to a OFPMP\_FLOW\_STATS multipart request consists of an array of the following:

The fields in this message have the same meanings as in the individual flow desc reply type (OFPMP\_FLOW\_DESC - see 7.3.5.2).

The reason field is one of the following:

The reason value OFPRR\_STATS\_REQUEST means that the message is a reply to a OFPMP\_FLOW\_STATS multipart request. The reason value OFPRR\_STAT\_TRIGGER means that the message is a status generated when one of the flow statistic threshold was crossed in a *stat trigger* instruction (see 7.2.5).

# 7.3.5.4 Aggregate Flow Statistics

Aggregate information about multiple flow entries is requested with the OFPMP\_AGGREGATE\_STATS multipart request type:

```
as an output port. A value of OFPP_ANY
                                indicates no restriction. */
   uint32_t out_group;
                              /* Require matching entries to include this
                                 as an output group. A value of OFPG_ANY
                                 indicates no restriction. */
    uint8_t pad2[4];
                              /* Align to 64 bits. */
    uint64_t cookie;
                             /* Require matching entries to contain this
                                 cookie value */
   uint64_t cookie_mask;
                             /* Mask used to restrict the cookie bits that
                                must match. A value of 0 indicates
                                no restriction. */
    struct ofp_match match;
                              /* Fields to match. Variable size. */
};
OFP_ASSERT(sizeof(struct ofp_aggregate_stats_request) == 40);
```

The fields in this message have the same meanings as in the individual flow desc request type (OFPMP\_FLOW\_DESC - see 7.3.5.2).

The body of the reply consists of the following:

```
/* Body of reply to OFPMP_AGGREGATE_STATS request. */
struct ofp_aggregate_stats_reply {
    struct ofp_stats stats; /* Aggregated statistics list. Variable size. */
};
OFP_ASSERT(sizeof(struct ofp_aggregate_stats_reply) == 8);
```

The stats field contains a list of OXS fields (see 7.2.4.2). The field OXS\_OF\_FLOW\_COUNT is mandatory and is equal to the number of flow entries that matched the request. The fields OXS\_OF\_PACKET\_COUNT and OXS\_OF\_BYTE\_COUNT are optional and count all packets processed by the all the flow entry matching the request.

# 7.3.5.5 Port Statistics

Information about port statistics is requested with the OFPMP\_PORT\_STATS multipart request type:

The port\_no field optionally filters the stats request to the given port. To request all port statistics, port\_no must be set to OFPP\_ANY.

The body of the reply consists of an array of the following:

```
/* Body of reply to OFPMP_PORT_STATS request. If a counter is unsupported,
* set the field to all ones. */
struct ofp_port_stats {
   uint16_t length;
                            /* Length of this entry. */
   uint8_t pad[2];
                            /* Align to 64 bits. */
   uint32_t port_no;
   uint32_t duration_sec; /* Time port has been alive in seconds. */
   uint32_t duration_nsec; /* Time port has been alive in nanoseconds beyond
                               duration_sec. */
                            /* Number of received packets. */
   uint64_t rx_packets;
   uint64_t tx_packets;
                           /* Number of transmitted packets. */
   uint64_t rx_bytes;
                            /* Number of received bytes. */
   uint64_t tx_bytes;
                            /* Number of transmitted bytes. */
   uint64_t rx_dropped;
                            /* Number of packets dropped by RX. */
   uint64_t tx_dropped;
                            /* Number of packets dropped by TX. */
                            /* Number of receive errors. This is a super-set
   uint64_t rx_errors;
                               of more specific receive errors and should be
                               greater than or equal to the sum of all
                               rx_*_err values in properties. */
   uint64_t tx_errors;
                            /* Number of transmit errors. This is a super-set
                               of more specific transmit errors and should be
                               greater than or equal to the sum of all
                               tx_*_err values (none currently defined.) */
   /* Port description property list - 0 or more properties */
   struct ofp_port_stats_prop_header properties[0];
};
OFP_ASSERT(sizeof(struct ofp_port_stats) == 80);
```

The duration\_sec and duration\_nsec fields indicate the elapsed time the port has been configured into the OpenFlow pipeline. The total duration in nanoseconds can be computed as  $duration\_sec \times 10^9 + duration\_nsec$ . Implementations are required to provide second precision; higher precision is encouraged where available.

The rx\_packets, tx\_packets, rx\_bytes and tx\_bytes are basic port counters measuring packets going through the port.

The properties field is a list of port statistics properties, which include port type specific statistics.

The list of port description property types that are currently defined are:

A property definition contains the property type, length, and any associated data:

```
/* Common header for all port stats properties. */
struct ofp_port_stats_prop_header {
                    type; /* One of OFPPSPT_*. */
   uint16_t
                    length; /* Length in bytes of this property. */
   uint16_t
OFP_ASSERT(sizeof(struct ofp_port_stats_prop_header) == 4);
The OFPPSPT_ETHERNET property uses the following structure and fields:
/* Ethernet port stats property. */
struct ofp_port_stats_prop_ethernet {
                          /* OFPPSPT_ETHERNET. */
   uint16_t
                type;
                    length; /* Length in bytes of this property. */
   uint16_t
                  pad[4]; /* Align to 64 bits. */
   uint8_t
   uint64_t rx_frame_err; /* Number of frame alignment errors. */
   uint64_t rx_over_err;
                           /* Number of packets with RX overrun. */
   uint64_t rx_crc_err;
                           /* Number of CRC errors. */
   uint64_t collisions;
                           /* Number of collisions. */
OFP_ASSERT(sizeof(struct ofp_port_stats_prop_ethernet) == 40);
The OFPPSPT_OPTICAL property uses the following structure and fields:
/* Optical port stats property. */
struct ofp_port_stats_prop_optical {
   uint16_t
              type; /* OFPPSPT_OPTICAL. */
                   length; /* Length in bytes of this property. */
   uint16_t
   uint8_t
                  pad[4]; /* Align to 64 bits. */
   uint32_t flags;
                           /* Features enabled by the port. */
   uint32_t tx_freq_lmda; /* Current TX Frequency/Wavelength */
   uint32_t tx_offset;
                           /* TX Offset */
   uint32_t tx_grid_span; /* TX Grid Spacing */
   uint32_t rx_freq_lmda; /* Current RX Frequency/Wavelength */
                           /* RX Offset */
   uint32_t rx_offset;
   uint32_t rx_grid_span; /* RX Grid Spacing */
                           /* Current TX power */
   uint16_t tx_pwr;
   uint16_t rx_pwr;
                           /* Current RX power */
   uint16_t bias_current; /* TX Bias Current */
   uint16_t temperature;
                           /* TX Laser Temperature */
OFP_ASSERT(sizeof(struct ofp_port_stats_prop_optical) == 44);
The flags indicates which of the stats values are valid:
/* Flags is one of OFPOSF_ below */
enum ofp_port_stats_optical_flags {
   OFPOSF_RX_TUNE = 1 << 0, /* Receiver tune info valid */
   OFPOSF_TX_TUNE = 1 << 1, /* Transmit tune info valid */
   OFPOSF_TX_PWR = 1 << 2, /* TX Power is valid */
   OFPOSF_RX_PWR = 1 << 4, /* RX power is valid */
   OFPOSF_TX_BIAS = 1 << 5, /* Transmit bias is valid */
   OFPOSF_TX_TEMP = 1 << 6, /* TX Temp is valid */
};
```

The port tuning values are represented as described by the Port Description (see 7.2.1). Frequency values are in MHz, wavelength (lambda) in nm \* 100. The tx\_pwr and rx\_pwr are dBm \* 10. The bias\_current is mA \* 10 and is useful as a laser efficiency reference. The laser temperature is degress C \* 10.

The OFPPSPT\_EXPERIMENTER property uses the following structure and fields:

```
/* Experimenter port stats property. */
struct ofp_port_stats_prop_experimenter {
                             /* OFPPSPT_EXPERIMENTER. */
    uint16_t
                  type;
                    length; /* Length in bytes of this property. */
    uint16_t
    uint32 t
                    experimenter; /* Experimenter ID which takes the same
                                       form as in struct
                                       ofp_experimenter_header. */
    uint32_t
                     exp_type;
                                    /* Experimenter defined. */
    /* Followed by:
         - Exactly (length - 12) bytes containing the experimenter data, then
        - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
                     experimenter_data[0];
    uint32 t
};
OFP_ASSERT(sizeof(struct ofp_port_stats_prop_experimenter) == 12);
```

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8).

#### 7.3.5.6 Port Description

The port description request OFPMP\_PORT\_DESCRIPTION enables the controller to get a description of all the standard ports of the OpenFlow switch (see 4.2). The request body consists of the following structure:

The port\_no field specify a valid port on the switch or can be set to OFPP\_ANY to refer to all ports on the switch.

The reply body consists of an array of the following:

```
/* Description of a port */
struct ofp_port {
    uint32_t port_no;
    uint16_t length;
    uint8_t pad[2];
    uint8_t hw_addr[OFP_ETH_ALEN];
    uint8_t pad2[2];
                                      /* Align to 64 bits. */
    char name[OFP_MAX_PORT_NAME_LEN]; /* Null-terminated */
                            /* Bitmap of OFPPC_* flags. */
    uint32_t config;
    uint32_t state;
                            /* Bitmap of OFPPS_* flags. */
    /* Port description property list - 0 or more properties */
    struct ofp_port_desc_prop_header properties[0];
};
OFP_ASSERT(sizeof(struct ofp_port) == 40);
```

This structure is the common port structure describing ports (see section 7.2.1), and includes port number, port config and port status. All port properties relevant to the port type must be included in the port description. For example, a physical port of type Ethernet must include a Ethernet property in its description, whereas a logical port does not need to include it.

The port description reply must include all the standard ports defined in the OpenFlow switch or attached to it, regardless of their state or configuration. It is recommended that the list of standard ports should not change dynamically, but only as the result of a network topology configuration or a switch configuration, for example using the OpenFlow Configuration Protocol (see 4.6).

#### 7.3.5.7 Queue Statistics

The OFPMP\_QUEUE\_STATS multipart request message provides queue statistics for one or more ports and one or more queues. The request body contains a port\_no field identifying the OpenFlow port for which statistics are requested, or OFPP\_ANY to refer to all ports. The queue\_id field identifies one of the priority queues, or OFPQ\_ALL to refer to all queues configured at the specified port. OFPQ\_ALL is Oxffffffff.

The body of the reply consists of an array of the following structure:

The duration\_sec and duration\_nsec fields indicate the elapsed time the queue has been installed in the switch. The total duration in nanoseconds can be computed as  $duration\_sec \times 10^9 + duration\_nsec$ . Implementations are required to provide second precision; higher precision is encouraged where available.

The properties field is a list of table feature properties, describing various capabilities of the table.

The list of table feature property types that are currently defined are:

```
enum ofp_queue_stats_prop_type {
    OFPQSPT_EXPERIMENTER = Oxffff /* Experimenter defined property. */
};
```

A property definition contains the property type, length, and any associated data:

The OFPQSPT\_EXPERIMENTER properties uses the following structure and fields:

```
/* Experimenter queue property description. */
struct ofp_queue_stats_prop_experimenter {
                            /* OFPQSPT_EXPERIMENTER. */
              type;
   uint16_t
                    length; /* Length in bytes of this property. */
   uint16_t
   uint32_t
                    experimenter; /* Experimenter ID which takes the same
                                      form as in struct
                                      ofp_experimenter_header. */
   uint32_t
                    exp_type;
                                   /* Experimenter defined. */
    /* Followed by:
        - Exactly (length - 12) bytes containing the experimenter data, then
        - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
                    experimenter_data[0];
   uint32_t
};
OFP_ASSERT(sizeof(struct ofp_queue_stats_prop_experimenter) == 12);
```

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8).

# 7.3.5.8 Queue Descriptions

An OpenFlow switch provides limited Quality-of-Service support (QoS) through a simple queuing mechanism.

A switch can optionally have one or more queues attached to a specific output port, and those queues can be used to schedule packets exiting the datapath on that output port. Each queue on the switch is uniquely identified by a *port number* and a *queue ID*. Two queues on different ports can have the same *queue ID*. Packets are directed to one of the queues based on the packet output port and the packet queue id, set using the *Output* action and *Set Queue* action respectively.

Packets mapped to a specific queue will be treated according to that queue's configuration (e.g. min rate). Queue processing happens logically after all pipeline processing. Packet scheduling using queues is not defined by this specification and is switch dependent, in particular no priority between *queue IDs* is assumed.

Queue configuration takes place outside the OpenFlow switch protocol, either through a command line tool or through an external dedicated configuration protocol. The controller can query the switch for configured queues on a port using OFPMP\_QUEUE\_DESC multipart request.

The OFPMP\_QUEUE\_DESC multipart request message provides queue descriptions for one or more ports and one or more queues. The request body contains a port\_no field identifying the OpenFlow port for which descriptions are requested, or OFPP\_ANY to refer to all ports. The queue\_id field identifies one of the priority queues, or OFPQ\_ALL to refer to all queues configured at the specified port. OFPQ\_ALL is Oxfffffff.

The body of the reply consists of an array of the following structure:

The properties field is a list of table feature properties, describing various capabilities of the table.

The list of table feature property types that are currently defined are:

```
enum ofp_queue_desc_prop_type {
                                /* Minimum datarate guaranteed. */
   OFPQDPT_MIN_RATE = 1,
                        = 2,
                                 /* Maximum datarate. */
    OFPQDPT_MAX_RATE
    OFPQDPT_EXPERIMENTER = Oxffff /* Experimenter defined property. */
};
A property definition contains the property type, length, and any associated data:
/* Common header for all queue properties */
struct ofp_queue_desc_prop_header {
                           /* One of OFPQDPT_*. */
   uint16_t
                    type;
   uint16_t
                    length; /* Length in bytes of this property. */
OFP_ASSERT(sizeof(struct ofp_queue_desc_prop_header) == 4);
The OFPQDPT_MIN_RATE properties uses the following structure and fields:
/* Min-Rate queue property description. */
struct ofp_queue_desc_prop_min_rate {
   uint16_t
               type; /* OFPQDPT_MIN_RATE. */
   uint16_t
                  length; /* Length is 8. */
   uint16_t rate; /* In 1/10 of a percent; >1000 -> disabled. */
                        /* 64-bit alignment */
   uint8_t pad[2];
};
OFP_ASSERT(sizeof(struct ofp_queue_desc_prop_min_rate) == 8);
If rate is not configured, it is set to OFPQ_MIN_RATE_UNCFG, which is 0xffff.
The OFPQDPT MAX RATE properties uses the following structure and fields:
/* Max-Rate queue property description. */
struct ofp_queue_desc_prop_max_rate {
             type; /* OFPQDPT_MAX_RATE. */
   uint16_t
   uint16_t
                  length; /* Length is 8. */
   uint16_t rate; /* In 1/10 of a percent; >1000 -> disabled. */
                        /* 64-bit alignment */
   uint8_t pad[2];
OFP_ASSERT(sizeof(struct ofp_queue_desc_prop_max_rate) == 8);
If rate is not configured, it is set to OFPQ_MAX_RATE_UNCFG, which is 0xffff.
The OFPQDPT_EXPERIMENTER properties uses the following structure and fields:
/* Experimenter queue property description. */
struct ofp_queue_desc_prop_experimenter {
                            /* OFPQDPT_EXPERIMENTER. */
   uint16_t
               type;
                  length; /* Length in bytes of this property. */
   uint16_t
   uint32_t
                  experimenter; /* Experimenter ID which takes the same
                                     form as in struct
                                     ofp_experimenter_header. */
   uint32 t
                    exp_type;
                                  /* Experimenter defined. */
    /* Followed by:
```

```
* - Exactly (length - 12) bytes containing the experimenter data, then
* - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
* bytes of all-zero bytes */
uint32_t experimenter_data[0];
};
OFP_ASSERT(sizeof(struct ofp_queue_desc_prop_experimenter) == 12);
```

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8).

# 7.3.5.9 Group Statistics

The OFPMP\_GROUP\_STATS multipart request message provides statistics for one or more groups. The request body consists of the following structure:

The group\_id field specifies a valid group on the switch or can be set to OFPG\_ALL to refer to all groups on the switch.

The body of the reply consists of an array of the following structure:

```
/* Body of reply to OFPMP_GROUP_STATS request. */
struct ofp_group_stats {
   uint16_t length;
                           /* Length of this entry. */
                          /* Align to 64 bits. */
   uint8_t pad[2];
   uint32_t group_id;
                          /* Group identifier. */
   uint32_t ref_count;
                           /* Number of flows or groups that directly forward
                               to this group. */
   uint8_t pad2[4];
                            /* Align to 64 bits. */
   uint64_t packet_count; /* Number of packets processed by group. */
   uint64_t byte_count;
                            /* Number of bytes processed by group. */
   uint32_t duration_sec;
                           /* Time group has been alive in seconds. */
   uint32_t duration_nsec; /* Time group has been alive in nanoseconds beyond
                               duration_sec. */
   struct ofp_bucket_counter bucket_stats[0]; /* One counter set per bucket. */
};
OFP_ASSERT(sizeof(struct ofp_group_stats) == 40);
```

The fields include the group\_id referencing the group, the ref\_count field counting the number of flow entries or groups referencing directly the group, the packet\_count, and the byte\_count fields counting all packets processed by the group.

The duration\_sec and duration\_nsec fields indicate the elapsed time the group has been installed in the switch. The total duration in nanoseconds can be computed as  $duration\_sec \times 10^9 + duration\_nsec$ .

Implementations are required to provide second precision; higher precision is encouraged where available.

The bucket\_stats field consists of an array of ofp\_bucket\_counter structs:

```
/* Used in group stats replies. */
struct ofp_bucket_counter {
    uint64_t packet_count;    /* Number of packets processed by bucket. */
    uint64_t byte_count;    /* Number of bytes processed by bucket. */
};
OFP_ASSERT(sizeof(struct ofp_bucket_counter) == 16);
```

# 7.3.5.10 Group Description

The OFPMP\_GROUP\_DESC multipart request message provides a way to list the set of groups on a switch, along with their corresponding bucket actions. The request body consists of the following structure:

The group\_id field specifies a valid group on the switch or can be set to OFPG\_ALL to refer to all groups on the switch.

The body of the reply consists of an array of the following structure:

```
/* Body of reply to OFPMP_GROUP_DESC request. */
struct ofp_group_desc {
                          /* Length of this entry. */
   uint16_t length;
   uint8_t type;
                          /* One of OFPGT_*. */
   uint8_t pad;
                          /* Pad to 64 bits. */
  uint8_t pad2[6];
                          /* Pad to 64 bits. */
   /* Followed by:
      - Exactly 'bucket_array_len' bytes containing an array of
        struct ofp_bucket.
      - Zero or more bytes of group properties to fill out the overall
        length in the length field. */
   struct ofp_bucket buckets[0]; /* List of buckets - 0 or more. */
   //struct ofp_group_prop_header properties[0];
OFP_ASSERT(sizeof(struct ofp_group_desc) == 16);
```

Fields for group description are the same as those used with the ofp\_group\_mod struct (see 7.3.4.3).

# 7.3.5.11 Group Features

The OFPMP\_GROUP\_FEATURES multipart request message provides a way to list the capabilities of groups on a switch. The request body is empty, while the reply body has the following structure:

The types field is a bitmap of group types supported by the switch. The bitmask uses the values from ofp\_group\_type as the number of bits to shift left for an associated group type. Experimenter types should *not* be reported via this bitmask. For example, OFPGT\_ALL would use the mask 0x00000001.

The capabilities field uses a combination of the following flags:

```
/* Group configuration flags */
enum ofp_group_capabilities {
    OFPGFC_SELECT_WEIGHT = 1 << 0, /* Support weight for select groups */
    OFPGFC_SELECT_LIVENESS = 1 << 1, /* Support liveness for select groups */
    OFPGFC_CHAINING = 1 << 2, /* Support chaining groups */
    OFPGFC_CHAINING_CHECKS = 1 << 3, /* Check chaining for loops and delete */
};</pre>
```

The max groups field is the maximum number of groups for each type of group.

The actions field is a set of bitmaps of actions supported by each group type. The first bitmap applies to the OFPGT\_ALL group type. The bitmask uses the values from ofp\_action\_type as the number of bits to shift left for an associated action. Experimenter actions should *not* be reported via this bitmask. For example, OFPAT\_OUTPUT would use the mask 0x00000001.

#### 7.3.5.12 Meter Statistics

The OFPMP\_METER\_STATS statistics request message provides statistics for one or more meters. The request body consists of a meter\_id field, which can be set to OFPM\_ALL to refer to all meters on the switch.

The body of the reply consists of an array of the following structure:

```
/* Body of reply to OFPMP_METER_STATS request. Meter statistics. */
struct ofp_meter_stats {
              meter_id;
   uint32_t
                                   /* Meter instance. */
   uint16_t
                                    /* Length in bytes of this stats. */
                  len;
   uint8_t
                  pad[6];
   uint32_t
                  ref_count;
                                    /* Number of flows or groups that
                                       directly reference this meter. */
              packet_in_count; /* Number of packets in input. */
   uint64_t
   uint64_t
                  byte_in_count; /* Number of bytes in input. */
   uint32_t duration_sec; /* Time meter has been alive in seconds. */
   uint32_t duration_nsec; /* Time meter has been alive in nanoseconds beyond
                               duration_sec. */
   struct ofp_meter_band_stats band_stats[0]; /* The band_stats length is
                                       inferred from the length field. */
};
OFP_ASSERT(sizeof(struct ofp_meter_stats) == 40);
```

The packet\_in\_count and the byte\_in\_count fields count all packets processed by the meter. The ref\_count field counts the number of flow entries or groups directly referencing the meter.

The duration\_sec and duration\_nsec fields indicate the elapsed time the meter has been installed in the switch. The total duration in nanoseconds can be computed as  $duration\_sec \times 10^9 + duration\_nsec$ . Implementations are required to provide second precision; higher precision is encouraged where available.

The band\_stats field consists of an array of ofp\_meter\_band\_stats structs:

The packet\_band\_count and byte\_band\_count fields count all packets processed by the band.

The order of the band statistics must be the same as in the OFPMP\_METER\_DESC multipart reply.

# 7.3.5.13 Meter Descriptions

The OFPMP\_METER\_DESC multipart request message provides configuration for one or more meters. The request body consists of a meter\_id field, which can be set to OFPM\_ALL to refer to all meters on the switch.

The body of the reply consists of an array of the following structure:

The fields are the same fields used for configuring the meter (see 7.3.4.5).

#### 7.3.5.14 Meter Features

The OFPMP\_METER\_FEATURES multipart request message provides the set of features of the metering subsystem. The request body is empty, and the body of the reply consists of the following structure:

The band\_types field is a bitmap of band types supported by the switch, the switch may have other constraints on how band types may be combined in a specific meter. The bitmask uses the values from ofp\_meter\_band\_type as the number of bits to shift left for an associated band type. Experimenter types should *not* be reported via this bitmask. For example, OFPMBT\_DROP would use the mask 0x00000002.

The capabilities field uses a combination of the following flags:

The features field uses a combination of the following flags:

```
/* Meter feature flags */
enum ofp_meter_feature_flags {
    OFPMFF_ACTION_SET = 1 << 0, /* Support meter action in action set. */
    OFPMFF_ANY_POSITION = 1 << 1, /* Support any position in action list. */
    OFPMFF_MULTI_LIST = 1 << 2, /* Support multiple actions in action list. */
};</pre>
```

#### 7.3.5.15 Controller Status Multipart

The OFPMP\_CONTROLLER\_STATUS multipart message allows a controller to request the status, the roles and the control channels of other controllers configured on the switch. The request body is empty. The reply body consists of a list of controller status structures (7.2.7), one for every configured controller.

The reason field in every controller status structure must be set to OFPCSR\_REQUEST in the multipart response.

#### 7.3.5.16 Table Statistics

Information about tables is requested with the OFPMP\_TABLE\_STATS multipart request type. The request does not contain any data in the body.

The body of the reply consists of an array of the following:

The array has one structure for each table supported by the switch. The entries are returned in the order that packets traverse the tables.

# 7.3.5.17 Table Description

The OFPMP\_TABLE\_DESC multipart request message provides a way to list the current configuration of the tables on a switch, which is set using the OFPT\_TABLE\_MOD message. The request body is empty, while the reply body is an array of the following structure:

Fields for table description are the same as those used with the ofp\_table\_mod struct (see 7.3.4.1).

#### 7.3.5.18 Table Features

The OFPMP\_TABLE\_FEATURES multipart type allows a controller to both query for the capabilities of existing tables, and to optionally ask the switch to reconfigure its tables to match a supplied configuration. In general, the table feature capabilities represents all possible features of a table, however some features may be mutually exclusive and the current capabilities structures do not allow representing such exclusions.

# 7.3.5.18.1 Table Features request and reply

If the OFPMP\_TABLE\_FEATURES request body is *empty* the switch will return an array of ofp\_table\_features structures containing the capabilities of the currently configured flow tables. The flow tables and the pipeline are unchanged by this operation.

If the request body contains an array of one or more ofp\_table\_features structures, the switch will attempt to change its flow tables to match the requested flow table configuration change. Support for such requests is optional, and is discouraged when another protocol is used to configure tables, such as the OpenFlow Configuration Protocol. If those requests are not supported, the switch must return an ofp\_error\_msg with OFPET\_BAD\_REQUEST type and OFPBRC\_BAD\_LEN code. If those requests are disabled, the switch must return an ofp\_error\_msg with OFPET\_TABLE\_FEATURES\_FAILED type and OFPTFFC\_EPERM code.

A request containing a set of ofp\_table\_features structures can enable, disable, modify flow tables, or it can replace the full pipeline, depending on the *command* in the request. The following *commands* are supported:

The command OFPTFC\_REPLACE configures the entire pipeline, and the set of flow tables in the pipeline must match the set in the request, or an error must be returned (see 7.5.4.14). The capability of all flow tables included in the request must be updated. In particular, if the requested configuration does not contain an ofp\_table\_features structure for one or more flow tables that the switch supports, these flow tables are to be removed from the pipeline if the configuration is successfully set.

The command OFPTFC\_MODIFY configures only the set of flow tables specified in the request, other flow tables not included in the request are unchanged and their presence in the pipeline unchanged. The capability of the flow tables included in the request must be updated. This command can be used to modify the capabilities of a single flow table. If a flow table in the request was not included in the pipeline, it remains excluded.

The command OFPTFC\_ENABLE inserts in the pipeline the flow tables specified in the request. The flow tables are inserted in the pipeline based in their *table-id* number. The capability of the flow tables included in the request are unchanged and must not be updated.

The command OFPTFC\_DISABLE removes from the pipeline the flow tables specified in the request. The capability of the flow tables included in the request are unchanged and must not be updated.

A successful configuration change will configure all flow tables in the request, that is, either all the flow tables specified in the request are modified or none. If the command modifies the features of flow tables, the new capabilities for each flow table must be either a superset of, or equal to the requested capabilities. If a table feature included in the request has an empty list of properties, the list of properties for that flow table is unchanged and only the other features of that flow table are updated. If the flow table configuration is successful, flow entries from flow tables that have been removed or flow tables that had their capabilities change between the prior and new configuration are removed from the flow table, however no ofp\_flow\_removed messages are sent. The switch then replies with the new configuration.

The switch must be able to set the requested configuration in its entirety, or return an error message (see 7.5.4.14). A switch may not support all commands listed above (see 7.5.4.14). For commands other than OFPTFC\_REPLACE, the switch may support a limited number of flow tables in each request (see 7.5.4.14).

Requests and replies containing ofp\_table\_features are expected to meet the following minimum requirements:

- The table\_id field value specified in each ofp\_table\_features structure should be unique amongst all ofp table features structures in the message.
- The properties field included in each ofp\_table\_features structure must either be empty or must contain exactly one of each of the ofp\_table\_feature\_prop\_type properties, with two exceptions. First, properties with the \_MISS suffix may be omitted if it is the same as the corresponding property for regular flow entries. Second, properties of type OFPTFPT\_EXPERIMENTER and OFPTFPT\_EXPERIMENTER\_MISS may be omitted or included many times. Ordering is unspecified, but implementers are encouraged to use the ordering listed in the specification (see 7.3.5.18.2).

A switch receiving a request that does not meet these requirements should return an error of type OFPET\_TABLE\_FEATURES\_FAILED with the appropriate error code (see 7.5.4.14).

The following structure describes the body of the table features request and reply:

If the OFPMP\_TABLE\_FEATURES reply, the array has one structure for each flow table supported by the switch. The entries are always returned in the order that packets traverse the flow tables.

The command field is the configuration operation requested (see above). Only the command field from the first ofp\_table\_features entry is used, and it applies to the whole request. The command fields from subsequent ofp\_table\_features entries are ignored. In table features replies, this field is reserved and should be set to 0 (see 7.1.3).

The name field is a null-terminated string containing a human-readable name for the flow table. The value of OFP\_MAX\_TABLE\_NAME\_LEN is 32.

The capabilities field is the set of configuration flags that are supported in a flow table configuration message (see 7.3.4.1).

The max\_entries field describes the maximum number of flow entries that can be inserted into that flow table. Due to limitations imposed by modern hardware, the max\_entries value should be considered advisory and a best effort approximation of the capacity of the flow table. Despite the high-level abstraction of a flow table, in practice the resource consumed by a single flow entry is not constant. For example, a flow entry might consume more than one entry, depending on its match parameters (e.g., IPv4 vs. IPv6). Also, flow tables that appear distinct at an OpenFlow-level might in fact share the same underlying physical resources. Further, on OpenFlow hybrid switches, those flow tables may be shared with non-OpenFlow functions. The result is that switch implementers should report an approximation of the total flow entries supported and controller writers should not treat this value as a fixed, physical constant.

All fields in ofp\_table\_features may be requested to be changed by the controller with the exception of the max\_entries field, this is read only and returned by the switch.

The features field is the set of features flags defining how the flow table can be used and what are its basic features. The following values are defined for that field:

```
/* Flags of features supported by the table. */
enum ofp_table_feature_flag {
    OFPTFF_INGRESS_TABLE = 1 << 0, /* Can be configured as ingress table. */
    OFPTFF_EGRESS_TABLE = 1 << 1, /* Can be configured as egress table. */
    OFPTFF_FIRST_EGRESS = 1 << 4, /* Is the first egress table. */
};</pre>
```

The flag OFPTFF\_INGRESS\_TABLE, if set, indicates that the flow table can be configured as an ingress flow table (see 5.12). Flow table 0 must have this flag set, i.e. flow table 0 can always be used as an ingress flow table. This flag usually can't be changed via a table features request.

The flag OFPTFF\_EGRESS\_TABLE, if set, indicates that the flow table can be configured as an egress flow table (see 5.12). Flow table 0 must have this flag unset, i.e. table 0 can never be used as an egress flow table. This flag usually can't be changed via a table feature request.

The flag OFPTFF\_FIRST\_EGRESS, if set, indicates that this flow table is the first egress table: when a a packet is output to a port, egress processing will start with this flow table (see 5.12). In a table feature reply, only a single flow table can have this flag set. This flag can be set on a flow table only if the flow table is capable of being an egress table, i.e. has the OFPTFF\_EGRESS\_TABLE flag set. When the flag OFPTFF\_FIRST\_EGRESS is set on a flow table to make it the first egress table, the flow table previously used as a first egress table, if any, must have its corresponding flag clear. If multiple flow tables have this flag set in a request, only the last one is set. If no flow table has the OFPTFF\_FIRST\_EGRESS flag set, no egress table is used: when a packet is output to a port, it is directly processed by the output port.

The properties field is a list of table feature properties, describing various capabilities of the flow table.

#### 7.3.5.18.2 Table Features properties

The list of table feature property types that are currently defined are:

```
/* Table Feature property types.
* Low order bit cleared indicates a property for a regular Flow Entry.
* Low order bit set indicates a property for the Table-Miss Flow Entry.
*/
enum ofp_table_feature_prop_type {
    OFPTFPT INSTRUCTIONS
                                   = 0, /* Instructions property. */
    OFPTFPT_INSTRUCTIONS_MISS
                                  = 1, /* Instructions for table-miss. */
                                  = 2, /* Next Table property. */
    OFPTFPT_NEXT_TABLES
                                  = 3, /* Next Table for table-miss. */
    OFPTFPT_NEXT_TABLES_MISS
                                  = 4, /* Write Actions property. */
    OFPTFPT_WRITE_ACTIONS
    OFPTFPT_WRITE_ACTIONS_MISS
                                  = 5,
                                        /* Write Actions for table-miss. */
    OFPTFPT_APPLY_ACTIONS
                                  = 6,
                                        /* Apply Actions property. */
    OFPTFPT_APPLY_ACTIONS_MISS
                                   = 7,
                                        /* Apply Actions for table-miss. */
    OFPTFPT_MATCH
                                  = 8, /* Match property. */
    OFPTFPT_WILDCARDS
                                  = 10, /* Wildcards property. */
    OFPTFPT_WRITE_SETFIELD
                                  = 12, /* Write Set-Field property. */
    OFPTFPT_WRITE_SETFIELD_MISS
                                  = 13, /* Write Set-Field for table-miss. */
    OFPTFPT_APPLY_SETFIELD
                                  = 14, /* Apply Set-Field property. */
    OFPTFPT APPLY SETFIELD MISS
                                  = 15, /* Apply Set-Field for table-miss. */
                                  = 16, /* Table synchronisation property. */
    OFPTFPT_TABLE_SYNC_FROM
    OFPTFPT_WRITE_COPYFIELD
                                   = 18, /* Write Copy-Field property. */
```

```
OFPTFPT_WRITE_COPYFIELD_MISS = 19, /* Write Copy-Field for table-miss. */
OFPTFPT_APPLY_COPYFIELD = 20, /* Apply Copy-Field property. */
OFPTFPT_APPLY_COPYFIELD_MISS = 21, /* Apply Copy-Field for table-miss. */
OFPTFPT_PACKET_TYPES = 22, /* Packet types property. */
OFPTFPT_EXPERIMENTER = 0xFFFE, /* Experimenter property. */
OFPTFPT_EXPERIMENTER_MISS = 0xFFFF, /* Experimenter for table-miss. */
};
```

The properties with the \_MISS suffix describe the capabilities for the table-miss flow entry (see 5.4), whereas other properties describe the capabilities for regular flow entry. If a specific property does not have any capability (for example no Set-Field support), a property with an empty list must be included in the property list. When a property of the table-miss flow entry is the same as the corresponding property for regular flow entries (i.e. both properties have the same list of capabilities), this table-miss property can be omited from the property list.

A property definition contains the property type, length, and any associated data:

The OFPTFPT\_INSTRUCTIONS and OFPTFPT\_INSTRUCTIONS\_MISS properties use the following structure and fields:

The instruction\_ids field is the list of instructions supported by this table (see 5.5). The elements of that list are variable in size to enable expressing experimenter instructions, non-experimenter instructions are 4 bytes, and they use the following structure:

The OFPTFPT\_NEXT\_TABLES, OFPTFPT\_NEXT\_TABLES\_MISS and OFPTFPT\_TABLE\_SYNC\_FROM properties use the following structure and fields:

```
/* Next Tables and Table Synchronise From properties */
struct ofp_table_feature_prop_tables {
                             /* One of OFPTFPT_NEXT_TABLES,
    uint16_t
                    type;
                                 OFPTFPT_NEXT_TABLES_MISS,
                                 OFPTFPT_TABLE_SYNC_FROM. */
   uint16_t
                    length; /* Length in bytes of this property. */
    /* Followed by:
        - Exactly (length - 4) bytes containing the table_ids, then
        - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
                    table_ids[0];
                                         /* List of table ids. */
    uint8_t
};
OFP_ASSERT(sizeof(struct ofp_table_feature_prop_tables) == 4);
```

For OFPTFPT\_NEXT\_TABLES and OFPTFPT\_NEXT\_TABLES\_MISS, the table\_ids field is the array of tables that can be directly reached from the present table using the OFPIT\_GOTO\_TABLE instruction (see 5.1).

For OFPTFPT\_TABLE\_SYNC\_FROM, the table\_ids field is the array of tables the present table is synchronising content from (see 6.6). When a flow entry is added, modified or removed in one of the flow tables listed in the array, a corresponding flow entry is automatically added, modified or removed in the present flow table.

The OFPTFPT\_WRITE\_ACTIONS, OFPTFPT\_WRITE\_ACTIONS\_MISS, OFPTFPT\_APPLY\_ACTIONS and OFPTFPT\_APPLY\_ACTIONS\_MISS properties use the following structure and fields:

```
/* Actions property */
struct ofp_table_feature_prop_actions {
   uint16 t
                              /* One of OFPTFPT_WRITE_ACTIONS,
                    type;
                                 OFPTFPT_WRITE_ACTIONS_MISS,
                                 OFPTFPT_APPLY_ACTIONS,
                                 OFPTFPT_APPLY_ACTIONS_MISS. */
    uint16_t
                     length; /* Length in bytes of this property. */
    /* Followed by:
        - Exactly (length - 4) bytes containing the action_ids, then
        - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
    struct ofp_action_id action_ids[0];
                                             /* List of actions */
OFP_ASSERT(sizeof(struct ofp_table_feature_prop_actions) == 4);
```

The OFPTFPT\_WRITE\_ACTIONS and OFPTFPT\_WRITE\_ACTIONS\_MISS properties describe actions supported by the table using the OFPIT\_WRITE\_ACTIONS instruction, whereas the OFPTFPT\_APPLY\_ACTIONS and OFPTFPT\_APPLY\_ACTIONS\_MISS properties describe actions supported by the table using the OFPIT\_APPLY\_ACTIONS instruction.

The action\_ids field represents all the actions supported by the feature (see 5.8). The elements of that list are variable in size to enable expressing experimenter actions, non-experimenter actions are 4 bytes, and they use the following structure:

The OFPTFPT\_MATCH, OFPTFPT\_WILDCARDS, OFPTFPT\_WRITE\_SETFIELD, OFPTFPT\_WRITE\_SETFIELD, OFPTFPT\_WRITE\_SETFIELD, MISS, OFPTFPT\_APPLY\_SETFIELD, OFPTFPT\_APPLY\_SETFIELD\_MISS, OFPTFPT\_APPLY\_COPYFIELD and OFPTFPT\_APPLY\_COPYFIELD\_MISS properties use the following structure and fields:

```
/* Match, Wildcard or Set-Field property */
struct ofp_table_feature_prop_oxm {
   uint16_t
                     type;
                              /* One of OFPTFPT_MATCH,
                                 OFPTFPT_WILDCARDS,
                                 OFPTFPT_WRITE_SETFIELD,
                                 OFPTFPT_WRITE_SETFIELD_MISS,
                                 OFPTFPT_APPLY_SETFIELD,
                                 OFPTFPT_APPLY_SETFIELD_MISS,
                                 OFPTFPT_WRITE_COPYFIELD,
                                 OFPTFPT_WRITE_COPYFIELD_MISS,
                                 OFPTFPT_APPLY_COPYFIELD,
                                 OFPTFPT_APPLY_COPYFIELD_MISS. */
   uint16_t
                     length; /* Length in bytes of this property. */
    /* Followed by:
        - Exactly (length - 4) bytes containing the oxm_ids, then
        - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
           bytes of all-zero bytes */
                     oxm_ids[0]; /* Array of OXM headers */
    uint32 t
OFP_ASSERT(sizeof(struct ofp_table_feature_prop_oxm) == 4);
```

The oxm\_ids field is the list of OXM types for the feature (see 7.2.3.2). The elements of that list are 32-bit OXM headers for non-experimenter OXM fields or 64-bit OXM headers for experimenter OXM fields, those OXM fields don't include any payload. The oxm\_length field in OXM headers must be the length value defined for the OXM field, i.e. the payload length if the OXM field had a payload. For experimenter OXM fields with variable payload size, the oxm\_length field must be the maximum length of the payload. In some cases, only the packet register with the highest type field needs to be included in the list (see 7.2.3.10).

The OFPTFPT\_MATCH property indicates the fields for which that particular table supports matching on (see 7.2.3.7). For example, if the table can match the ingress port, an OXM header with the type OXM\_OF\_IN\_PORT should be included in the list. If the HASMASK bit is set on the OXM header then the switch must support masking for the given type. Fields that are not listed in this property can not be used in the table as a match field, unless they are used as a prerequisite for another field. Fields that can only be used in the table as prerequisite and can't match other values must not be included in this property (see 7.2.3.6). For example, if a table matches IPv4 addresses for IP packets and can't match arbitrary Ethertypes, the table must accept the prerequisite of Ethertype equal to IPv4 in the match, however the Ethertype field must not be listed in this property. On the other hand, if the table matches

IPv4 addresses for IP packets and can match arbitrary Ethertypes, the Ethertype field must be listed in this property.

The OFPTFPT\_WILDCARDS property indicates the fields for which that particular table supports wildcarding (omitting) in the match when their prerequisite can be met. This property must be a strict subset of the OFPTFPT\_MATCH property. For example, a direct look-up hash table would have that list empty, while a TCAM or sequentially searched table would have it set to the same value as the OFPTFPT\_MATCH property. If a field can be omitted only when one of its prerequisites is invalid (a prerequisite field has a value different from its required value), and must be always present when its prerequisites can be met, it must not be included in the OFPTFPT\_WILDCARDS property. For example, if TCP ports can be omitted when the IP protocol is TCP, they would be included in this property. On the other hand if the TCP ports need to be present every time the IP protocol is TCP and are omitted only when the IP protocol is different from TCP (such as UDP), they would not be included in this property.

The OFPTFPT\_WRITE\_SETFIELD and OFPTFPT\_WRITE\_SETFIELD\_MISS properties describe Set-Field action types supported by the table using the OFPIT\_WRITE\_ACTIONS instruction, whereas the OFPTFPT\_APPLY\_SETFIELD and OFPTFPT\_APPLY\_SETFIELD\_MISS properties describe Set-Field action types supported by the table using the OFPIT\_APPLY\_ACTIONS instruction (see 7.2.6.7). If the HASMASK bit is set in the OXM header, then the switch must support partial rewrite for the given type (see 7.2.6.7).

The OFPTFPT\_WRITE\_COPYFIELD and OFPTFPT\_WRITE\_COPYFIELD\_MISS properties describe *Copy-Field* action types supported by the table using the OFPIT\_WRITE\_ACTIONS instruction, whereas the OFPTFPT\_APPLY\_COPYFIELD and OFPTFPT\_APPLY\_COPYFIELD\_MISS properties describe *Copy-Field* action types supported by the table using the OFPIT\_APPLY\_ACTIONS instruction (see 7.2.6.8).

The OFPTFPT\_APPLY\_ACTIONS, OFPTFPT\_APPLY\_ACTIONS\_MISS, OFPTFPT\_APPLY\_SETFIELD, and OFPTFPT\_APPLY\_SETFIELD\_MISS properties contain actions and fields the table is capable of applying. For each of these lists, if an element is present it means the table is at least capable of applying the element in isolation one time. There is currently no way to indicate which elements can be applied together, in which order, and how many times an element can be applied in a single flow entry.

The OFPTFPT\_PACKET\_TYPES property uses the following structure and fields:

```
/* Packet types property */
struct ofp_table_feature_prop_oxm_values {
                     type;
                              /* OFPTFPT_PACKET_TYPES. */
    uint16_t
    uint16_t
                     length; /* Length in bytes of this property. */
    /* Followed by:
         - Exactly (length - 4) bytes containing the oxm values, then
         - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
           bytes of all-zero bytes */
                     oxm_values[0];
                                      /* Array of OXM values */
    uint32_t
};
OFP_ASSERT(sizeof(struct ofp_table_feature_prop_oxm_values) == 4);
```

The oxm\_values is the list of OXM values for the feature (see 7.2.3.2). The elements of that list are complete OXM fields including OXM header and payload.

The OFPTFPT\_PACKET\_TYPES property contains the set of *Packet Types Match Field* values supported by the table (see 7.2.3.11), defining the packet types supported by the table. For each packet type supported

by the table, it either includes one OXM\_OF\_PACKET\_TYPE field (64 bit long) or one experimenter OXM field. This property must be included if the table matches packet types other than Ethernet packets. This version of the specification supports only a single Packet Type per switch, having multiple Packet Types in this property is outside the scope of the specification.

The OFPTFPT\_EXPERIMENTER and OFPTFPT\_EXPERIMENTER\_MISS properties use the following structure and fields:

```
/* Experimenter table feature property */
struct ofp_table_feature_prop_experimenter {
   uint16_t
                             /* One of OFPTFPT_EXPERIMENTER,
                    type;
                                 OFPTFPT_EXPERIMENTER_MISS. */
   uint16_t
                    length; /* Length in bytes of this property. */
   uint32_t
                     experimenter; /* Experimenter ID which takes the same
                                       form as in struct
                                       ofp_experimenter_header. */
    uint32_t
                                    /* Experimenter defined. */
                     exp_type;
    /* Followed by:
        - Exactly (length - 12) bytes containing the experimenter data, then
        - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
                    experimenter_data[0];
    uint32 t
};
OFP_ASSERT(sizeof(struct ofp_table_feature_prop_experimenter) == 12);
```

The experimenter field is the Experimenter ID and the exp\_type field is the experimenter type, they takes the same form as in the typical experimenter structure (see 7.2.8). The experimenter\_data field is experimenter defined, the whole property need to be padded to 64 bits.

### 7.3.5.19 Flow Monitoring

The OFPMP\_FLOW\_MONITOR multipart type allows a controller to manage flow monitors, that keep track of changes to the flow tables. In a multi-controller deployment, this enables a controller to be aware of changes made to the flow tables by other controllers. A controller can create a number of flow monitors, each flow monitor matching a subset of flow entries in some flow tables. Flow monitors will generate events for any change to the flow tables matching one of the monitor.

Flow monitoring is an optional feature and may not be supported by all OpenFlow switches. The number of flow monitors that can be created on a switch may also be limited.

#### 7.3.5.19.1 Flow Monitoring Request

Flow monitor configuration is done with a OFPMP FLOW MONITOR multipart request.

```
/* Body for ofp_multipart_request of type OFPMP_FLOW_MONITOR.

* The OFPMP_FLOW_MONITOR request's body consists of an array of zero or more
* instances of this structure. The request arranges to monitor the flows
* that match the specified criteria, which are interpreted in the same way as
* for OFPMP_FLOW.
*
```

```
* 'id' identifies a particular monitor for the purpose of allowing it to be
* canceled later with OFPFMC_DELETE. 'id' must be unique among
* existing monitors that have not already been canceled.
struct ofp_flow_monitor_request {
   uint32_t monitor_id;
                               /* Controller-assigned ID for this monitor. */
   uint32_t out_port;
                               /* Required output port, if not OFPP_ANY. */
   uint32_t out_group;
                               /* Required group number, if not OFPG_ANY. */
   uint16_t flags;
                               /* OFPFMF_*. */
                               /* One table's ID or OFPTT_ALL (all tables). */
   uint8_t table_id;
                               /* One of OFPFMC_*. */
   uint8_t command;
   struct ofp_match match;
                               /* Fields to match. Variable size. */
OFP_ASSERT(sizeof(struct ofp_flow_monitor_request) == 24);
```

The monitor\_id field uniquely identifies a monitor for a specific controller connection within a switch. The same monitor\_id can be reused for different monitors by two different controller connections on the same switch

The command field must be one of the following:

The command OFPFMC\_ADD creates a new flow monitor and begins to monitor flow entries based on the request parameters. The command OFPFMC\_ADD must return an error if the monitor\_id specified is already in use (see 7.5.4.17). The command OFPFMC\_DELETE destroys the flow monitor specified by monitor\_id and stops the associated flow monitoring and flow monitor events. The command OFPFMC\_MODIFY is equivalent to deleting and creating a flow monitor.

The table\_id field specifies the flow table to monitor. If this field is set to OFPTT\_ALL, all tables are monitored.

The match field contains a description of the flow entries that should be monitored and may contain wildcarded and masked fields. This field's matching behavior is described in Section 6.4.

The out\_port and out\_group fields optionally reduce the scope of the flow monitor by output port. If either out\_port or out\_group contains a value other than OFPP\_ANY or OFPG\_ANY respectively, it introduces an additional constraint when matching flow entries to monitors. This constraint is that the flow entry must contain an output action directed at that port or that group before or after the change triggering the flow monitor event.

The flags field only applies to flow monitor creation and may include the following flags:

```
/* 'flags' bits in struct of_flow_monitor_request. */
enum ofp_flow_monitor_flags {
    /* When to send updates. */
    OFPFMF_INITIAL = 1 << 0,    /* Initially matching flows. */</pre>
```

When the OFPFMF\_INITIAL flag is set, the switch must include, in the reply to the flow monitor request, all flow entries matching the new monitor at the time of the request.

When the OFPFMF\_ADD flag is set, the flow monitor must match all additions of flow entries, for example flow mod with OFPFC\_ADD command. When the OFPFMF\_REMOVED flag is set, the flow monitor must match all removal of flow entries, for example flow mod with OFPFC\_DELETE or OFPFC\_DELETE\_STICT commands, flow expiry due to timeout, evictions, or group or meter deletions. When the OFPFMF\_MODIFY flag is set, the flow monitor must match all modifications of flow entries, for example flow mod requests with OFPFC\_MODIFY or OFPFC\_MODIFY\_STICT commands.

Flow updates of type OFPFMF\_REMOVED and flow removed messages (see 7.4.2) are independent notification mechanisms. Flow updates do not take into account the value of the OFPFF\_SEND\_FLOW\_REM flag on the flow entry. A single flow entry may be reported by both notification mechanism.

When the OFPFMF\_INSTRUCTIONS flag is set, the switch must include the flow entry instructions in the flow monitor events. If this flag is unset, the switch must omit the flow entry instructions in the flow monitor events.

When the <code>OFPFMF\_NO\_ABBREV</code> flag is set, the switch must not use abbreviated flow updates in events. If this flag is unset, the switch must use abbreviated flow updates in events related to flow table changes done by the controller that created the flow monitor.

When the OFPFMF\_ONLY\_OWN flag is set, the switch must generate updates only for flow table changes done by the controller that created the flow monitor. If this flag is unset, the switch must generate updates for flow table changes done by all controllers.

### 7.3.5.19.2 Flow Monitoring Reply

When the switch received a OFPMP\_FLOW\_MONITOR multipart request, it replies to it using a OFPMP\_FLOW\_MONITOR multipart reply, the transaction id (xid) of this reply must be the same as the request. All flow entries that match one flow monitor of the request with the flag OFPFMF\_INITIAL set must be included in the reply as a flow update (with event type OFPFME\_INITIAL).

The OFPMP\_FLOW\_MONITOR multipart reply is also used as an asynchronous message. At any time, whenever a change to a flow table matches some outstanding flow monitor, the switch must send a notification to the controller using a OFPMP\_FLOW\_MONITOR multipart reply, the transaction id (xid) of this reply must be 0. All flow entries that match one outstanding flow monitor must be included in the reply. For example, if a flow\_mod request modifies multiple flow entries that match some flow monitors, the notification must include one flow update for each flow entry matching a flow monitor.

If a modified flow entry matches multiple flow monitor, it must be included only once in the notification. The flow update must include the aggregate of all information specified by the matched flow monitors.

For example, if any of the matching flow monitors specifies instructions (OFPFMF\_INSTRUCTIONS), the flow update must include instructions, and if any of the matching flow monitors specifies full changes for the controller's own changes (OFPFMF\_NO\_ABBREV), the controller's own changes will be included in full.

A flow\_mod message that does not change the flow table will not trigger any notification, even an abbreviated one. For example, a "modify" or "delete" flow\_mod message that does not match any flow entries will not trigger a notification. Whether an "add" or "modify" flow\_mod message, that specifies all the same parameters that a flow entry already has, triggers a notification is unspecified and subject to change in future versions of this specification.

A OFPMP\_FLOW\_MONITOR multipart reply can not cross a barrier handshake (see 7.3.7). The switch must always send the OFPMP\_FLOW\_MONITOR multipart reply for a given flow table change before the reply to a OFPT\_BARRIER\_REQUEST request that follows the request responsible for the flow table change.

The body of any OFPMP\_FLOW\_MONITOR multipart reply consists of an array of flow updates. All flow updates contains the update type and length:

The event field is the flow update type. The list of flow update types that are currently defined are:

```
/* 'event' values in struct ofp_flow_update_header. */
enum ofp_flow_update_event {
   /* struct ofp_flow_update_full. */
   OFPFME_INITIAL = 0, /* Flow present when flow monitor created. */
   OFPFME ADDED = 1,
                              /* Flow was added. */
   OFPFME_REMOVED = 2,
                              /* Flow was removed. */
   OFPFME_MODIFIED = 3,
                              /* Flow instructions were changed. */
   /* struct ofp_flow_update_abbrev. */
   OFPFME\_ABBREV = 4,
                              /* Abbreviated reply. */
   /* struct ofp_flow_update_header. */
                      /st Monitoring paused (out of buffer space). st/
   OFPFME_PAUSED = 5,
   OFPFME_RESUMED = 6,
                              /* Monitoring resumed. */
};
```

The OFPFME\_ADDED, OFPFME\_REMOVED and OFPFME\_MODIFIED types denotes flow entries matching a flow monitor that have been respectively added, removed or modified in the flow tables and matching an active flow monitor. The OFPFME\_INITIAL denotes flow updates part of the initial reply for flow monitors with the flag OFPFMF\_INITIAL set. They use the following structure and fields:

```
/* OFPMP_FLOW_MONITOR reply for OFPFME_INITIAL, OFPFME_ADDED, OFPFME_REMOVED,
 * and OFPFME_MODIFIED. */
struct ofp_flow_update_full {
   uint16_t length;
                               /* Length is 32 + match + instructions. */
                               /* One of OFPFME_*. */
   uint16_t event;
   uint8_t table_id;
                               /* ID of flow's table. */
   uint8_t reason;
                               /* OFPRR_* for OFPFME_REMOVED, else zero. */
   uint16_t idle_timeout;
                              /* Number of seconds idle before expiration. */
   uint16_t hard_timeout;
                               /* Number of seconds before expiration. */
   uint16_t priority;
                               /* Priority of the entry. */
   uint8_t zeros[4];
                               /* Reserved, currently zeroed. */
                               /* Opaque controller-issued identifier. */
   uint64_t cookie;
                               /* Fields to match. Variable size. */
   struct ofp_match match;
          Instruction set.
          If OFPFMF_INSTRUCTIONS was not specified, or 'event' is
          OFPFME_REMOVED, no instructions are included.
   //struct ofp_instruction instructions[0];
};
OFP_ASSERT(sizeof(struct ofp_flow_update_full) == 32);
```

The fields consist of those provided in the flow\_mod that created the flow entry (see 7.3.4.2). For updates of type OFPFME\_REMOVED, the reason field is the removal reason (see 7.4.2), for other types this field must be zero.

The OFPFME\_ABBREV type denotes an abreviated flow update. When the controller does not specify OFPFMF\_NO\_ABBREV in a monitor request, any flow tables changes due to the controller's own requests (on the same OpenFlow channel) will be abbreviated, when possible. It uses the following structure and fields:

```
/* OFPMP_FLOW_MONITOR reply for OFPFME_ABBREV.
* When the controller does not specify OFPFMF_OWN in a monitor request, any
* flow tables changes due to the controller's own requests (on the same
* OpenFlow channel) will be abbreviated, when possible, to this form, which
* simply specifies the 'xid' of the OpenFlow request (e.g. an OFPT_FLOW_MOD)
* that caused the change.
* Some changes cannot be abbreviated and will be sent in full.
*/
struct ofp_flow_update_abbrev {
   uint16_t length;
                               /* Length is 8. */
                               /* OFPFME_ABBREV. */
   uint16_t event;
   uint32_t xid;
                               /* Controller-specified xid from flow_mod. */
OFP_ASSERT(sizeof(struct ofp_flow_update_abbrev) == 8);
```

The xid field is the transaction id of the controller request this update relates to.

The OFPFME\_PAUSED and OFPFME\_RESUMED types denotes monitoring pause and resume due to buffer management constraints. They use the following structure and fields:

### 7.3.5.19.3 Flow Monitoring Pause

OpenFlow messages for flow monitor notifications can overflow the buffer space available to the switch, either temporarily (e.g. due to network conditions slowing OpenFlow traffic) or more permanently (e.g. the sustained rate of flow table change exceeds the network bandwidth between switch and controller). The flow monitoring pause mechanism disables flow updates when the number of queued flow updates reaches a limit, and enables the switch and controller to recover gracefully. The pause mechanism guarantees that the maximum buffer space requirement for flow updates to be bounded by the limit plus the maximum number of supported flow entries.

When the switch's notification buffer space reaches a switch defined limiting threshold, the switch must reacts as follows:

- 1. The switch must send a OFPFME\_PAUSED flow update to the controller, following all the already queued flow updates. After it receives this message, the controller knows that its view of the flow table, as represented by flow monitor notifications, is incomplete.
- 2. As long as the notification buffer is not empty:
  - OFPFMF\_ADD and OFPFMF\_MODIFY flow updates must not be sent.
  - OFPFMF\_REMOVED flow updates must still be sent, but only for flow entries that existed before the switch sent the OFPFME\_PAUSED flow update.
  - OFPFMF\_ABBREV flow updates must follow the same rules, in particular flow updates related to adding or modifying flow entries must not be sent.
- 3. When the notification buffer empties, the switch must send OFPFME\_ADDED flow updates for flow entries added since the buffer reached its limit and still present in a flow table, and it must send OFPFME\_MODIFIED flow updates for flow entries that existed before the limit was reached, changed after the limit was reached and still present in a flow table.
- 4. The switch must send a OFPFME\_RESUMED flow update to the controller. After it receives this message, the controller knows that its view of the flow table, as represented by flow monitor notifications, is again complete.

# 7.3.5.20 Bundle Features Multipart

The bundle features request, using the OFPMP\_BUNDLE\_FEATURES message type, allows a controller to query a switch about its bundle capabilities, including whether it supports atomic bundles, ordered bundles, and scheduled bundles.

# 7.3.5.20.1 Bundle Features Request Message Format

The body of the bundle features request message is defined by struct ofp\_bundle\_features\_request, as follows:

```
/* Body of OFPMP_BUNDLE_FEATURES request. */
struct ofp_bundle_features_request {
    uint32_t feature_request_flags; /* Bitmap of "ofp_bundle_feature_flags". */
    uint8_t pad[4];

    /* Bundle features property list - 0 or more. */
    struct ofp_bundle_features_prop_header properties[0];
};
OFP_ASSERT(sizeof(struct ofp_bundle_features_request) == 8);
```

The body consists of a flags field, followed by zero or more property TLV fields. The bundle features properties are specified in Section 7.3.5.20.3. The flags field, feature\_request\_flags, is defined as follows:

- OFPBF\_TIMESTAMP indicates that the current request includes a timestamp, i.e., the current time according to the controller's clock. The timestamp is incorporated in the ofp\_bundle\_features\_prop\_time property.
- OFPBF\_TIME\_SET\_SCHED indicates that the request includes the scheduling tolerance parameters, sched\_max\_future and sched\_max\_past, and that the switch should update its scheduling tolerance according to the received values.

If at least one of the flags OFPBF\_TIMESTAMP or OFPBF\_TIME\_SET\_SCHED is set, the bundle features request includes a ofp\_bundle\_features\_prop\_time property.

#### 7.3.5.20.2 Bundle Features Reply Message Format

A switch that receives a bundle features request and processes it successfully sends a bundle features reply to the controller. The bundle features reply is an OFPT\_MULTIPART\_REPLY message with a type OFPMP\_BUNDLE\_FEATURES. The body of the bundle features reply message is struct ofp\_bundle\_features, as follows:

```
/* Body of reply to OFPMP_BUNDLE_FEATURES request. */
struct ofp_bundle_features {
    uint16_t capabilities; /* Bitmap of "ofp_bundle_flags". */
    uint8_t pad[6];

    /* Bundle features property list - 0 or more. */
    struct ofp_bundle_features_prop_header properties[0];
};
OFP_ASSERT(sizeof(struct ofp_bundle_features) == 8);
```

The capabilities field indicates the bundle-related features that are supported by the switch. The format of the capabilities field is defined by struct ofp\_bundle\_flags, as follows:

```
/* Bundle configuration flags. */
enum ofp_bundle_flags {
    OFPBF_ATOMIC = 1 << 0, /* Execute atomically. */
    OFPBF_ORDERED = 1 << 1, /* Execute in specified order. */
    OFPBF_TIME = 1 << 2, /* Execute in specified time. */
};</pre>
```

- OFPBF\_ATOMIC and OFPBF\_ORDERED indicate that the switch supports atomic bundles, and ordered bundles, respectively (see Section 6.9.4).
- OFPBF\_TIME indicates that the switch supports scheduled bundles, as described in Section 6.9.6. When this flag is set, the bundle features reply message includes the ofp\_bundle\_features\_prop\_time property.

The bundle features reply message may include zero or more properties. The format of the bundle features properties is defined below.

If a switch receives a bundle features request and is unable to process it, it replies with an error message of type OFPET\_BAD\_REQUEST (see 7.5.4.2). The code OFPBRC\_MULTIPART\_BAD\_SCHED indicates that the request had the OFPBF\_TIME\_SET\_SCHED flag enabled, and the switch failed to update the scheduling tolerance values.

### 7.3.5.20.3 Bundle Features Properties

Bundle features properties are optional TLV fields with a common header format, as follows:

# 7.3.5.20.4 The Bundle Features Time Property

A bundle feature request in which at least one of the flags OFPBF\_TIMESTAMP or OFPBF\_TIME\_SET\_SCHED is set, incorporates the ofp\_bundle\_features\_prop\_time property. A bundle feature reply that has the OFPBF\_TIME flag set incorporates the ofp\_bundle\_features\_prop\_time property.

The ofp\_bundle\_features\_prop\_time property is defined as follows:

```
/* Bundle time features. */
struct ofp_bundle_features_prop_time {
                                      /* OFPTMPBF_TIME_CAPABILITY. */
   uint16_t type;
   uint16_t length;
                                      /* Length in bytes of this property. */
   uint8_t pad[4];
    struct ofp_time sched_accuracy; /* The scheduling accuracy, i.e., how
                                       * accurately the switch can perform a
                                       * scheduled commit. This field is used
                                       * only in bundle features replies, and
                                       * is ignored in bundle features
                                       * requests. */
    struct ofp_time sched_max_future; /* The maximal difference between the
                                      * scheduling time and the current time.*/
    struct ofp_time sched_max_past; /* If the scheduling time occurs in the
                                      * past, defines the maximal difference
                                       * between the current time and the
                                       * scheduling time.*/
    struct ofp_time timestamp;
                                     /* Indicates the time during the
                                       * transmission of this message.*/
OFP_ASSERT(sizeof(struct ofp_bundle_features_prop_time) == 72);
```

Time is represented using struct ofp\_time, as defined in Section 7.3.9.5.

The ofp\_bundle\_features\_prop\_time property in a bundle features request includes:

- sched\_accuracy: this field is relevant only to bundle features replies, and the switch must ignore this field in a bundle features request.
- sched\_max\_future and sched\_max\_past: a switch that receives a bundle features request with OFPBF\_TIME\_SET\_SCHED set should attempt to change its scheduling tolerance values according to the sched\_max\_future and sched\_max\_past values from the time property. If the switch does not successfully update its scheduling tolerance values, it replies with an error message of type OFPET\_BAD\_REQUEST, and with the OFPBRC\_MULTIPART\_BAD\_SCHED code.
- timestamp, indicating the controller's time during the transmission of this message. A switch that receives a bundle features request with OFPBF\_TIMESTAMP set may use the received timestamp to roughly estimate the offset between its clock and the controller's clock.

The ofp\_bundle\_features\_prop\_time property in a bundle features reply includes:

• sched\_accuracy, indicating the estimated scheduling accuracy of the switch. For example, if the value of sched\_accuracy is 1000000 nanoseconds (1 ms), it means that when the switch receives a bundle commit scheduled to time  $T_s$ , the commit will in practice be invoked at  $T_s \pm 1$  ms. The factors that affect the scheduling accuracy are discussed in Section 6.9.6.3.

- sched\_max\_future and sched\_max\_past, containing the scheduling tolerance values of the switch. If the corresponding bundle features request has the OFPBF\_TIME\_SET\_SCHED flag enabled, these two fields are identical to the ones sent be the controller in the request.
- timestamp, indicating the switch's time during the transmission of this feature reply. Every bundle feature reply that includes the time property also includes a timestamp. The timestamp may be used by the controller to get a rough estimate of whether the switch's clock is synchronized to the controller's.

# 7.3.5.21 Experimenter Multipart

Experimenter-specific multipart messages are requested with the OFPMP\_EXPERIMENTER multipart type. The first bytes of the request and reply bodies are the following structure:

```
/* Body for ofp_multipart_request/reply of type OFPMP_EXPERIMENTER. */
struct ofp_experimenter_multipart_header {
   uint32_t experimenter;    /* Experimenter ID. */
   uint32_t exp_type;    /* Experimenter defined. */
   /* Experimenter-defined arbitrary additional data. */
};
OFP_ASSERT(sizeof(struct ofp_experimenter_multipart_header) == 8);
```

The experimenter field is the Experimenter ID and the exp\_type field is the experimenter type, they takes the same form as in the typical experimenter structure (see 7.2.8).

The rest of the request and reply bodies are experimenter-defined and don't need to be padded.

# 7.3.6 Packet-Out Message

When the controller wishes to send a packet out through the datapath, it uses the OFPT\_PACKET\_OUT message:

```
/* Send packet (controller -> datapath). */
struct ofp_packet_out {
   struct ofp_header header;
   uint32_t buffer_id;
                                 /* ID assigned by datapath (OFP_NO_BUFFER
                                    if none). */
   uint16_t actions_len;
                                 /* Size of action array in bytes. */
   uint8_t pad[2];
                                /* Align to 64 bits. */
   struct ofp_match match;
                               /* Packet pipeline fields. Variable size. */
   /* The variable size and padded match is followed by the list of actions. */
   /* struct ofp_action_header actions[0]; *//* Action list - 0 or more. */
   /* The variable size action list is optionally followed by packet data.
    * This data is only present and meaningful if buffer_id == -1. */
   /* uint8_t data[0]; */ /* Packet data. The length is inferred
                                    from the length field in the header. */
OFP_ASSERT(sizeof(struct ofp_packet_out) == 24);
```

The buffer\_id is the same given in the ofp\_packet\_in message. If the buffer\_id is OFP\_NO\_BUFFER, then the packet data is included in the data array, and the packet encapsulated in the message is processed by the actions of the message. OFP\_NO\_BUFFER is Oxffffffff. If buffer\_id is valid, the corresponding packet is removed from the buffer and processed by the actions of the message.

The match field is a set of OXM TLVs containing the pipeline fields associated with the packet. The TLVs in the match field define the value of the pipeline fields that must be associated with the packet for OpenFlow processing. The OXM TLVs must include the *Packet Type Match Field* to identify the packet type included in the data field, unless the packet is Ethernet (see 7.2.3.11). The match field can only include pipeline fields, and must not include any header fields (see 7.2.3.7). If the match field contains any header fields, the switch must refuse the ofp\_packet\_out message and send a *Pipeline Fields Only* error message (see 7.5.4.2).

If the packet was received at the controller via an ofp\_packet\_in message, the match field should be set using the pipeline field values given in the ofp\_packet\_in message (see 7.4.1).

Pipeline fields not included in the match field must be set to zero by the switch, except for OXM\_OF\_IN\_PORT that is mandatory and for OXM\_OF\_IN\_PHY\_PORT that must be set to the value of OXM\_OF\_IN\_PORT.

The OXM\_OF\_IN\_PORT TLV included in the match field specifies the ingress port that must be associated with the packet for OpenFlow processing. This TLV is mandatory in the match field, and it must be set to either a valid standard switch port (see 4.2) or OFPP\_CONTROLLER. For example, the value of this TLV is used when processing the packet using groups, OFPP\_TABLE, OFPP\_IN\_PORT and OFPP\_ALL. If OXM\_OF\_IN\_PORT TLV is not included in the match field, the switch must refuse the ofp\_packet\_out message and send a *Bad Port* error message (see 7.5.4.2).

The action field is a list of actions defining how the packet should be processed by the switch. It may include packet modification, group processing and an output port. The list of actions of an OFPT\_PACKET\_OUT message can also specify the OFPP\_TABLE reserved port as an output action to process the packet through the OpenFlow pipeline, starting at the first flow table (see 4.5). If OFPP\_TABLE is specified, the match field is used as the set of pipeline fields in the flow table lookup.

If any action in the list of actions is not valid or supported, the switch must generate an error message with type as OFPET\_BAD\_ACTION (see 7.5.4.3).

In some cases, packets sent to OFPP\_TABLE may be forwarded back to the controller as the result of a flow entry action or table miss. Detecting and taking action for such controller-to-switch loops is outside the scope of this specification. In general, OpenFlow messages are not guaranteed to be processed in order, therefore if a OFPT\_PACKET\_OUT message using OFPP\_TABLE depends on a flow that was recently sent to the switch (with a OFPT\_FLOW\_MOD message), a OFPT\_BARRIER\_REQUEST message may be required prior to the OFPT\_PACKET\_OUT message to make sure the flow entry was committed to the flow table prior to execution of OFPP\_TABLE.

The data field is either empty, or when buffer\_id is OFP\_NO\_BUFFER the data field contains the packet to be processed. The packet type is determined by the *Packet Type Match Field* included in the match field, if no Packet Type Match Field is present the packet must be Ethernet (Ethernet frame, including an Ethernet header and Ethernet payload, but no Ethernet FCS - see 7.2.3.11). The only processing done by the switch on the packet is processing explicitly specified by the OpenFlow actions in the action field, is particular the switch must not transparently set the Ethernet source address or IP checksum.

# 7.3.7 Barrier Message

When the controller wants to control message processing and ordering by the switch, it may use an OFPT\_BARRIER\_REQUEST message. This message has no body and is only composed of an OpenFlow header.

The first function of barrier message is to ensure message ordering, so that message dependencies are not violated (see 6.2). The second function of barrier message is for the controller to receive notifications for completed operations. The third function of barrier is to ensure that the state sent by the controller is committed to the datapath.

When the switch receives a OFPT\_BARRIER\_REQUEST message on a connection, the switch must finish processing all previously-received messages on that connection, including sending corresponding reply or error messages, before executing the barrier request or any messages on the connection received after the Barrier Request. If all previously-received messages have already been processed when the switch receives a barrier request, the switch can execute the barrier request immediately. When the processing of all message prior to the barrier is complete, the switch executes the barrier request, all state changes corresponding to messages prior to the barrier request must be committed to the datapath, so that any packet received by the switch after sending the barrier response must be processed by the datapath updated with the state changes of all messages prior to the barrier command (this requirement does not apply to packets in flight or queued through the pipeline when the barrier request is executed). When the execution of the barrier request is done, the switch must send an OFPT\_BARRIER\_REPLY message with the xid of the original barrier request. The barrier reply must be sent after the reply or error messages corresponding to messages prior to the barrier request. After sending the barrier reply, the switch can process normally all message after the barrier request (see 6.2).

# 7.3.8 Role Request Message

When the controller wants to change its role, it uses the OFPT\_ROLE\_REQUEST message with the following structure:

The field role is the new role that the controller wants to assume, and can have the following values:

If the role value in the message is OFPCR\_ROLE\_MASTER or OFPCR\_ROLE\_SLAVE, the switch must validate generation\_id to check for stale messages (see 6.3.6). If the validation fails, the switch must discard the role request and return a *Stale* error message (see 7.5.4.12).

If the role value is OFPCR\_ROLE\_MASTER, all other controllers whose role was OFPCR\_ROLE\_MASTER are changed to OFPCR\_ROLE\_SLAVE (see 6.3.6). If the role value is OFPCR\_ROLE\_NOCHANGE, the current role of the controller is not changed; this enables a controller to query its current role without changing it.

Upon receipt of a OFPT\_ROLE\_REQUEST message, if there is no error, the switch must return a OFPT\_ROLE\_REPLY message. The structure of this message is exactly the same as the OFPT\_ROLE\_REQUEST message, and the field role is the current role of the controller. The field generation\_id is set to the current generation\_id (the generation\_id associated with the last successful role request with role OFPCR\_ROLE\_MASTER or OFPCR\_ROLE\_SLAVE), if the current generation\_id was never set by a controller, the field generation\_id in the reply must be set to the maximum field value (the unsigned equivalent of -1).

If the switch must change the role of another controller from OFPCR\_ROLE\_MASTER to OFPCR\_ROLE\_SLAVE, it must send that controller a OFPT\_ROLE\_STATUS message (see 7.4.4).

The OFPT\_ROLE\_REQUEST message also sets the short\_id for the controller. This ID, if defined, uniquely identifies a particular controller. The ID is initially OFPCID\_UNDEFINED, and controllers may set the short\_id to a value they choose, or set it to OFPCID\_UNDEFINED if they do not wish to use it. Only the OFPCID\_UNDEFINED ID may be assigned to more than one controller, and setting the short\_id to a value already in use will cause the entire OFPT\_ROLE\_REQUEST message to be rejected (see 7.5.4.12). OFPCID\_UNDEFINED is 0.

## 7.3.9 Bundle messages

# 7.3.9.1 Bundle control messages

The controller can create, destroy and commit bundles with the OFPT\_BUNDLE\_CONTROL request. The OFPT\_BUNDLE\_CONTROL message uses the following structure:

```
/* Message structure for OFPT_BUNDLE_CONTROL. */
struct ofp_bundle_ctrl_msg {
   struct ofp_header
                         header;
   uint32_t
                          bundle_id;
                                          /* Identify the bundle. */
                                          /* OFPBCT_*. */
   uint16_t
                          type;
                                          /* Bitmap of OFPBF_* flags. */
    uint16_t
                          flags;
    /* Bundle Property list. */
    struct ofp_bundle_prop_header properties[0]; /* Zero or more properties. */
OFP_ASSERT(sizeof(struct ofp_bundle_ctrl_msg) == 16);
```

The bundle\_id field is the bundle identifier, a 32 bit number chosen by the controller. The bundle identifier should be unique over the connection during the bundle lifetime.

The type field is the control message type. The control types that are currently defined are:

```
/* Bundle control message types */
enum ofp_bundle_ctrl_type {
    OFPBCT_OPEN_REQUEST = 0,
    OFPBCT_OPEN_REPLY = 1,
    OFPBCT_CLOSE_REQUEST = 2,
    OFPBCT_CLOSE_REPLY = 3,
    OFPBCT_COMMIT_REQUEST = 4,
    OFPBCT_COMMIT_REPLY = 5,
    OFPBCT_DISCARD_REQUEST = 6,
    OFPBCT_DISCARD_REPLY = 7,
};
```

The flags field is a bitmask of bundle flags (see 7.3.9.3).

The properties field is a list of bundle properties (see 7.3.9.4).

# 7.3.9.2 Bundle Add message

The controller can add requests to a bundle using the OFPT\_BUNDLE\_ADD\_MESSAGE message. The OFPT\_BUNDLE\_ADD\_MESSAGE message uses the following structure:

```
/* Message structure for OFPT_BUNDLE_ADD_MESSAGE.
* Adding a message in a bundle is done with. */
struct ofp_bundle_add_msg {
   struct ofp_header
                         header;
   uint32_t
                                        /* Identify the bundle. */
                         bundle_id;
                                         /* Align to 64 bits. */
   uint16_t
                         pad;
                                         /* Bitmap of OFPBF_* flags. */
   uint16_t
                         flags;
    struct ofp_header
                         message;
                                          /* Message added to the bundle. */
    /* If there is one property or more, 'message' is followed by:
        - Exactly (message.length + 7)/8*8 - (message.length) (between 0 and 7)
          bytes of all-zero bytes */
    /* Bundle Property list. */
    /*struct ofp_bundle_prop_header properties[0];*/ /* Zero or more
                                                        properties. */
OFP_ASSERT(sizeof(struct ofp_bundle_add_msg) == 24);
```

The bundle\_id field is the bundle identifier, a 32 bit number chosen by the controller. The bundle identifier should be a bundle that has been previously opened and not yet closed.

The flags field is a bitmask of bundle flags (see 7.3.9.3).

The message is a OpenFlow message to be added to the bundle, it can be any OpenFlow message that the switch can support in a bundle. The field xid in the message must be identical to the field xid of the OFPT\_BUNDLE\_ADD\_MESSAGE message.

The properties field is a list of bundle properties (see 7.3.9.4).

# 7.3.9.3 Bundle flags

Bundle flags enable to modify the behaviour of a bundle.

The bundle flags that are currently defined are:

```
/* Bundle configuration flags. */
enum ofp_bundle_flags {
    OFPBF_ATOMIC = 1 << 0, /* Execute atomically. */
    OFPBF_ORDERED = 1 << 1, /* Execute in specified order. */
    OFPBF_TIME = 1 << 2, /* Execute in specified time. */
};</pre>
```

- OFPBF\_ATOMIC is set to request fully atomic application of the bundle.
- OFPBF\_ORDERED is set to request the message of the bundle are applied strictly in order.
- OFPBF\_TIME is used in a bundle commit message to indicate that the commit message includes the bundle's execution time, using ofp\_bundle\_prop\_time. For further details about scheduled bundles, see Section 6.9.6.

The bundle flags OFPBF\_ATOMIC and OFPBF\_ORDERED must be specified on every bundle message part of the bundle, and they need to be consistent. The flag OFPBF\_TIME can be set only in bundle commit messages, and should be ignored by the receiver in other bundle messages.

#### 7.3.9.4 Bundle properties

The list of bundle property types that are currently defined are:

A property definition contains the property type, length, and any associated data:

The ofp\_bundle\_prop\_time property is included in bundle messages that have the OFPBF\_TIME flag set. This property is used in scheduled bundles, as described in Section 6.9.6. This property can only be included in bundle commit messages. The OFPBPT\_TIME property uses the following structure and fields:

The scheduled\_time field specifies the time at which the switch is expected to perform the scheduled bundle. The format of this field is ofp\_time, defined in Section 7.3.9.5.

The OFPBPT EXPERIMENTER property uses the following structure and fields:

```
/* Experimenter bundle property */
struct ofp_bundle_prop_experimenter {
    uint16_t
                     type;
                              /* OFPBPT_EXPERIMENTER. */
    uint16_t
                     length; /* Length in bytes of this property. */
    uint32 t
                     experimenter; /* Experimenter ID which takes the same
                                       form as in struct
                                       ofp_experimenter_header. */
    uint32_t
                                    /* Experimenter defined. */
                     exp_type;
    /* Followed by:
        - Exactly (length - 12) bytes containing the experimenter data, then
        - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
    uint32_t
                     experimenter_data[0];
};
OFP_ASSERT(sizeof(struct ofp_bundle_prop_experimenter) == 12);
```

The experimenter field is the Experimenter ID, which takes the same form as in struct ofp\_experimenter.

#### 7.3.9.5 Time Format

Bundle commit request messages may include the scheduled\_time, which specifies when the bundle should be committed. The scheduled\_time field uses struct ofp\_time. The time format, ofp\_time, is also used in bundle features messages (see 7.3.5.20.4).

The time format, ofp\_time, is based on the format defined in the IEEE 1588-2008 standard. It consists of two subfields; a seconds field, representing the integer portion of time in seconds<sup>1</sup>, and a nanoseconds field, representing the fractional portion of time in nanoseconds, i.e.,  $0 \le nanoseconds \le (10^9 - 1)$ .

```
/* Time Format. */
struct ofp_time {
    uint64_t seconds;
    uint32_t nanoseconds;
    uint8_t pad[4];
};
OFP_ASSERT(sizeof(struct ofp_time)==16);
```

<sup>&</sup>lt;sup>1</sup>The seconds field in IEEE 1588-2008 is 48 bits long. The seconds field defined here is a 64-bit field, but it has the same semantics as the seconds field in the IEEE 1588-2008 time format.

As defined in the IEEE 1588-2008 standard, time is measured according to the International Atomic Time (TAI) timescale. The origin of the timescale, also known as the epoch, is defined as 1 January 1970 00:00:00 TAI; at every instant, time is represented by the number of seconds that have elapsed since the epoch.

#### 7.3.9.6 Creating and opening a bundle

To create a bundle, the controller sends a OFPT\_BUNDLE\_CONTROL message with type OFPBCT\_OPEN\_REQUEST. The switch must create a new bundle with id bundle\_id attached to the current connection, with the options specified in the flags and properties. If the operation is successful, OFPT\_BUNDLE\_CONTROL message with type OFPBCT\_OPEN\_REPLY must be returned by the switch. If an error arises, an error message is returned.

The arguments of the Bundle Open Request must be validated and errors returned if they are not supported (see 7.5.4.18).

If the bundle\_id already refers to an existing bundle attached to the same connection, the switch must refuse to open the new bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_ID code. The existing bundle identified by bundle\_id must be discarded.

If the switch can not open this bundle because its having too many opened bundles on the switch or attached to the current connection, the switch must refuse to open the new bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_OUT\_OF\_BUNDLES code. If the switch can not open the bundle because the connection is using an unreliable transport, the switch must refuse to open the new bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC OUT OF BUNDLES code.

If the flags field request some feature that can not be implemented by the switch, the switch must refuse to open the new bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_FLAGS code.

#### 7.3.9.7 Adding messages to a bundle

The switch adds message to a bundle using the OFPT\_BUNDLE\_ADD\_MESSAGE. After the bundle is opened, the controller can sends a sequence of OFPT\_BUNDLE\_ADD\_MESSAGE messages to populate the bundle. Each OFPT\_BUNDLE\_ADD\_MESSAGE includes an OpenFlow message, this OpenFlow message is validated, and if successful it is stored in the bundle specified by bundle\_id on the current connection. If a message validation error or a bundle error condition arise, an error message is returned (see 7.5.4.18).

Message validation includes at minimum syntax checking and that all features are supported, and it may optionally include checking resource availability (see 6.9.3). If a message fails validation, an error message must be returned. The error message must use the xid of the offending message, the error data field corresponding to that message and the error code corresponding to the validation failure.

If the bundle\_id refers to a bundle that does not exist on the current connection, the corresponding bundle is created using arguments from the OFPT\_BUNDLE\_ADD\_MESSAGE message. If an error arise from creating the bundle, the relevant error message is returned (see 7.3.9.6). No OFPT\_BUNDLE\_CONTROL message with type OFPBCT\_OPEN\_REPLY is returned by the switch in this case.

If the bundle\_id refers to a bundle that is already closed, the switch must refuse to add the message to the bundle, discard the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BUNDLE\_CLOSED code.

If the flags field is different from the flags that were specified when the bundle was opened, the switch must refuse to add the message to the bundle, discard the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_FLAGS code.

If the message in the request is normally supported on the switch but is not supported in a bundle, the switch must refuse to add the message to the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_MSG\_UNSUP code. This is the case for hello, echo, and bundle messages, messages that are not requests (for example replies, status and errors messages), or if the implementation does not support including a specific modification message in a bundle.

If the message in the request is incompatible with another message already stored in the bundle, the switch must refuse to add the message to the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_MSG\_CONFLICT code.

If the bundle is full and can not fit the message in the request, the switch must refuse to add the message to the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_MSG\_TOO\_MANY code.

If the message in the request does not have a valid length field, the switch must refuse to add the message to the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_MSG\_BAD\_LEN code.

Message added in a bundle should have a unique xid to help matching errors to messages, except for multipart messages part of the same sequence, and the xid of the bundle add message must be the same as the embedded message. A switch may optionally verify that the two xid of a message are consistent or that two non-multipart messages of the bundle don't have the same xid, and if this is not the case refuse to add the new message to the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_MSG\_BAD\_XID code.

### 7.3.9.8 Closing a bundle

To finish recording a bundle, the controller may sends a OFPT\_BUNDLE\_CONTROL message with type OFPBCT\_CLOSE\_REQUEST. The switch must close the bundle specified by bundle\_id on the current connection. After closing the bundle, it can no longer be modified and no messages can be added to it, it can only be committed or discarded. Closing a bundle is optional. If the operation is successful, OFPT\_BUNDLE\_CONTROL message with type OFPBCT\_CLOSE\_REPLY must be returned by the switch. If an error arises, an error message is returned (see 7.5.4.18).

If the bundle\_id refers to a bundle that does not exist, the switch must reject the request and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_ID code.

If the bundle\_id refers to a bundle that is already closed, the switch must refuse to close to the bundle, discard the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BUNDLE\_CLOSED code.

If the flags field is different from the flags that were specified when the bundle was opened, the switch must refuse to close to the bundle, discard the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_FLAGS code.

The switch may optionally do additional validation of the messages part of the bundle as the result of the close request, such as validating resource availability. For each message that fails this additional validation, an error message must be generated that refer to the offending message. After sending those individual error messages, the switch must discard the bundle and send an additional ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_MSG\_FAILED code.

### 7.3.9.9 Committing Bundles

To finish and apply the bundle, the controller sends a OFPT\_BUNDLE\_CONTROL message with type OFPBCT\_COMMIT\_REQUEST. The switch must commit the bundle specified by bundle\_id on the current connection, it must apply all messages stored in the bundle as a single operation or return an error. The commit operation and the way the message part of the bundle are applied depend on the bundle flags (see 7.3.9.3). If the bundle was not closed prior to this request, it is automatically closed (see 7.3.9.8).

The commit is successful only if all messages parts of the bundle can be applied without error. If the bundle does not contain any message, commit is always successful. If the commit is successful, the switch must apply all messages of the bundle as a single operation, and a OFPT\_BUNDLE\_CONTROL message with type OFPBCT\_COMMIT\_REPLY must be returned by the switch. The OFPT\_BUNDLE\_CONTROL message with type OFPBCT\_COMMIT\_REPLY must be sent to the controller after the processing of all messages part of the bundle are guaranteed to no longer fail or produce an error.

If one or more message part of the bundle can not be applied without error, for example due to resource availability, the commit fails and all messages part of the bundle must be discarded without being applied. When the commit fails, the switch must generate an error message corresponding to the message that could not be applied. The error message must use the xid of the offending message, the error data field corresponding to that message and the error code corresponding to the failure. If multiple messages are generating errors, the switch may return only the first error found or generate multiple error messages for the same bundle. After sending those individual error messages, the switch must send an additional ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_MSG\_FAILED code.

After a commit operation, the bundle is discarded, whether the commit was successful or not. After receiving a successful reply or error message for this operation, the controller can reuse the bundle id.

Modification requests may require replies to be returned to the controller or events to be generated. Because any message of the bundle may fail, replies and events can only be generated once all modifications in the bundle have been applied. For replies, each of these replies contains the transaction ID of the corresponding request.

If the bundle\_id refers to a bundle that does not exist, the switch must reject the request and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_ID code.

If the flags field is different from the flags that were specified when the bundle was opened, the switch must refuse to commit the bundle, discard the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_FLAGS code.

#### 7.3.9.10 Discarding Bundles

To finish and discard the bundle, the controller sends a OFPT\_BUNDLE\_CONTROL message with type OFPBCT\_DISCARD\_REQUEST. The switch must discard the bundle specified by bundle\_id on the current connection, and all messages part of the bundle are discarded. If the operation is successful, a OFPT\_BUNDLE\_CONTROL message with type OFPBCT\_DISCARD\_REPLY must be returned by the switch. If an error arises, an error message is returned. After receiving either a successful reply or an error message, the controller can reuse the bundle\_id.

All implementations must be able to process a discard request on a existing bundle on the current connection without triggering errors. If the bundle\_id refers to a bundle that does not exist, the switch must reject the request and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_ID code.

#### 7.3.9.11 Other bundle error conditions

If a OFPT\_BUNDLE\_CONTROL message contains an invalid type, the switch must reject the request and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_TYPE code.

If a OFPT\_BUNDLE\_CONTROL or OFPT\_BUNDLE\_ADD\_MESSAGE message specifies flags different for those already specified on an existing bundle, the switch must reject the request and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_FLAGS code. An exception to the latter is the OFPBF\_TIME flag, which may have a different value in a bundle commit request message than in previous bundle messages, as described in 7.3.9.3.

If the switch does not receive any OFPT\_BUNDLE\_CONTROL or OFPT\_BUNDLE\_ADD\_MESSAGE message for an opened bundle\_id for a switch defined time greater than 1s, it may send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_TIMEOUT code. If the switch does not receive any new message in a bundle for a switch defined time greater than 1s, it may send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_TIMEOUT code.

If an OpenFlow message can not be processed because a bundle is locking a resource this message is using, the switch must reject that message and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BUNDLE\_IN\_PROGRESS code. If a switch can not process other messages between opening a bundle and either committing it or discarding it, the switch must reject that message and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BUNDLE\_IN\_PROGRESS code.

If a switch receives a scheduled commit and is not able to execute it, it sends an error message with type OFPET\_BUNDLE\_FAILED. The following error codes are specific to scheduled bundles:

- OFPBFC\_SCHED\_NOT\_SUPPORTED this code is used when the switch does not support scheduled bundle execution and receives a commit message with the OFPBF\_TIME flag set.
- OFPBFC\_SCHED\_FUTURE used when the switch receives a scheduled commit message and the scheduling time exceeds sched\_max\_future (see Section 6.9.6.4).

• OFPBFC\_SCHED\_PAST - used when the switch receives a scheduled commit message and the scheduling time exceeds sched max past (see Section 6.9.6.4).

# 7.3.10 Set Asynchronous Configuration Message

The switch manages a per-controller asynchronous configuration, which defines the asynchronous messages that it wants to receive (other than error messages) on a given OpenFlow channel. The controller is able to set and query its asynchronous configuration with the OFPT\_SET\_ASYNC and OFPT\_GET\_ASYNC\_REQUEST messages, respectively. The switch responds to a OFPT\_GET\_ASYNC\_REQUEST message with an OFPT\_GET\_ASYNC\_REPLY message; it does not reply to a request to set the configuration.

The OFPT\_SET\_ASYNC message sets whether a controller should receive a given asynchronous message that is generated by the switch. Other OpenFlow features control whether a given message is generated; for example, the OFPFF\_SEND\_FLOW\_REM flag in each flow entry controls whether the switch generates a OFPT\_FLOW\_REMOVED message when a flow entry is removed. The asynchronous configuration acts as an additional per-controller filter; for example it defines if a specific controller receives those OFPT\_FLOW\_REMOVED messages.

The configuration set with the OFPT\_SET\_ASYNC message is specific to a particular OpenFlow channel. It does not affect any other OpenFlow channels, whether currently established or to be established in the future. The configuration set with OFPT\_SET\_ASYNC does not filter or otherwise affect error messages.

A switch configuration, for example using the OpenFlow Configuration Protocol, may set the initial configuration of asynchronous messages when an OpenFlow connection is established. In the absence of such switch configuration, the initial configuration shall be:

- In the "master" or "equal" role, enable all OFPT\_PACKET\_IN messages, except those with reason OFPR\_INVALID\_TTL, enable all OFPT\_PORT\_STATUS, OFPT\_FLOW\_REMOVED, OFPT\_CONTROLLER\_STATUS messages, and disable all OFPT\_ROLE\_STATUS and OFPT\_REQUESTFORWARD messages.
- In the "slave" role, enable all OFPT\_PORT\_STATUS and OPFT\_CONTROLLER\_STATUS messages and disable all OFPT\_PACKET\_IN, OFPT\_FLOW\_REMOVED, OFPT\_ROLE\_STATUS and OFPT\_REQUESTFORWARD messages.

There is no body for OFPT\_GET\_ASYNC\_REQUEST beyond the OpenFlow header. The OFPT\_SET\_ASYNC and OFPT\_GET\_ASYNC\_REPLY messages have the following format:

The properties field is a list of asynchronous configuration properties, describing if various set of asynchronous messages are enabled or not. In a OFPT\_SET\_ASYNC, only the properties that shall be changed need to be included, properties that are omitted from the message are unchanged. In a OFPT\_GET\_ASYNC\_REPLY message, all properties must be included.

The asynchronous configuration types currently defined are:

```
/* Async Config property types.
 * Low order bit cleared indicates a property for the slave role.
 * Low order bit set indicates a property for the master/equal role.
enum ofp_async_config_prop_type {
                                = 0, /* Packet-in mask for slave. */
    OFPACPT_PACKET_IN_SLAVE
    OFPACPT_PACKET_IN_MASTER
                                = 1, /* Packet-in mask for master. */
    OFPACPT_PORT_STATUS_SLAVE
                                = 2, /* Port-status mask for slave. */
    OFPACPT_PORT_STATUS_MASTER
                               = 3, /* Port-status mask for master. */
    OFPACPT_FLOW_REMOVED_SLAVE
                                = 4, /* Flow removed mask for slave. */
    OFPACPT_FLOW_REMOVED_MASTER = 5, /* Flow removed mask for master. */
    OFPACPT ROLE STATUS SLAVE
                                = 6, /* Role status mask for slave. */
    OFPACPT_ROLE_STATUS_MASTER
                                = 7, /* Role status mask for master. */
    OFPACPT_TABLE_STATUS_SLAVE
                                = 8, /* Table status mask for slave. */
    OFPACPT_TABLE_STATUS_MASTER = 9, /* Table status mask for master. */
    OFPACPT_REQUESTFORWARD_SLAVE = 10, /* RequestForward mask for slave. */
    OFPACPT_REQUESTFORWARD_MASTER = 11, /* RequestForward mask for master. */
    OFPACPT FLOW STATS SLAVE
                                = 12, /* Flow stats mask for slave. */
    OFPACPT_FLOW_STATS_MASTER
                                = 13, /* Flow stats mask for master. */
    OFPACPT_CONT_STATUS_SLAVE
                                = 14, /* Controller status mask for slave. */
    OFPACPT_CONT_STATUS_MASTER = 15, /* Controller status mask for master. */
    OFPACPT_EXPERIMENTER_SLAVE = OxFFFE, /* Experimenter for slave. */
    OFPACPT_EXPERIMENTER_MASTER = OxFFFF, /* Experimenter for master. */
};
```

Each property type control whether the controller receives asynchronous messages with a specific enum ofp\_type. The properties with the \_MASTER suffix specifies messages of interest when the controller has a OFPCR\_ROLE\_EQUAL or OFPCR\_ROLE\_MASTER role (see ). The properties with the \_SLAVE suffix specifies messages of interest when the controller has a OFPCR\_ROLE\_SLAVE role.

A property definition contains the property type, length, and any associated data:

The OFPACPT\_PACKET\_IN\_SLAVE, OFPACPT\_PACKET\_IN\_MASTER, OFPACPT\_PORT\_STATUS\_SLAVE, OFPACPT\_PORT\_STATUS\_MASTER, OFPACPT\_FLOW\_REMOVED\_SLAVE, OFPACPT\_FLOW\_REMOVED\_MASTER, OFPACPT\_ROLE\_STATUS\_SLAVE and OFPACPT\_ROLE\_STATUS\_MASTER, OFPACPT\_TABLE\_STATUS\_SLAVE, OFPACPT\_TABLE\_STATUS\_MASTER, OFPACPT\_REQUESTFORWARD\_SLAVE, OFPACPT\_REQUESTFORWARD\_MASTER, OFPACPT\_FLOW\_STATS\_SLAVE, OFPACPT\_FLOW\_STATS\_MASTER, OPFT\_CONT\_STATUS\_SLAVE and OPFT\_CONT\_STATUS\_MASTER properties use the following structure and fields:

```
/* Various reason based properties */
struct ofp_async_config_prop_reasons {
   uint16_t
                              /* One of OFPACPT_PACKET_IN_*,
                     type;
                                 OFPACPT_PORT_STATUS_*,
                                 OFPACPT_FLOW_REMOVED_*,
                                 OFPACPT_ROLE_STATUS_*,
                                 OFPACPT_TABLE_STATUS_*,
                                 OFPACPT_REQUESTFORWARD_*,
                                 OFPACPT_FLOW_STATS_*,
                                 OFPACPT_CONT_STATUS_*. */
    uint16_t
                     length; /* Length in bytes of this property. */
   uint32_t
                              /* Bitmasks of reason values. */
OFP_ASSERT(sizeof(struct ofp_async_config_prop_reasons) == 8);
```

The mask field is a bit-mask in which a 0-bit disables receiving a message sent with the reason code corresponding to the bit index and a 1-bit enables receiving it. For example, if the property type is  $OFPACPT_PORT_STATUS_SLAVE$ , the bit with value  $2^2 = 4$  in mask determines whether the controller will receive  $OFPT_PORT_STATUS$  messages with reason  $OFPPR_MODIFY$  (value 2) when the controller has role  $OFPCR_ROLE_SLAVE$ .

The OFPACPT\_EXPERIMENTER\_SLAVE and OFPACPT\_EXPERIMENTER\_MASTER properties uses the following structure and fields:

```
/* Experimenter async config property */
struct ofp_async_config_prop_experimenter {
                              /* One of OFPTFPT_EXPERIMENTER_SLAVE,
   uint16_t
                    type;
                                 OFPTFPT_EXPERIMENTER_MASTER. */
   uint16_t
                    length; /* Length in bytes of this property. */
    uint32_t
                     experimenter; /* Experimenter ID which takes the same
                                       form as in struct
                                       ofp_experimenter_header. */
   uint32_t
                                    /* Experimenter defined. */
                     exp_type;
    /* Followed by:
        - Exactly (length - 12) bytes containing the experimenter data, then
        - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
                     experimenter_data[0];
};
OFP_ASSERT(sizeof(struct ofp_async_config_prop_experimenter) == 12);
```

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8).

# 7.4 Asynchronous Messages

# 7.4.1 Packet-In Message

When packets are received by the datapath and sent to the controller, they use the OFPT\_PACKET\_IN message:

```
/* Packet received on port (datapath -> controller). */
struct ofp_packet_in {
   struct ofp_header header;
                           /* ID assigned by datapath. */
   uint32_t buffer_id;
   uint16_t total_len;
                           /* Full length of frame. */
   uint8_t reason;
                           /* Reason packet is being sent (one of OFPR_*) */
   uint8_t table_id;
                           /* ID of the table that was looked up */
                          /* Cookie of the flow entry that was looked up. */
   uint64_t cookie;
   struct ofp_match match; /* Packet metadata. Variable size. */
   /* The variable size and padded match is always followed by:
        - Exactly 2 all-zero padding bytes, then
        - An Ethernet frame whose length is inferred from header.length.
    * The padding bytes preceding the Ethernet frame ensure that the IP
    * header (if any) following the Ethernet header is 32-bit aligned.
    */
   //uint8_t pad[2];
                           /* Align to 64 bit + 16 bit */
                           /* Ethernet frame */
   //uint8_t data[0];
OFP_ASSERT(sizeof(struct ofp_packet_in) == 32);
```

The buffer\_id is an opaque value used by the datapath to identify a buffered packet. If the packet associated with the packet-in message is buffered, the buffer\_id must be an identifier unique on the current connection referring to that packet on the switch. If the packet is not buffered - either because of no available buffers, or because of being explicitly requested via OFPCML\_NO\_BUFFER - the buffer\_id must be OFP\_NO\_BUFFER.

Switches that implement buffering are expected to expose, through documentation, both the amount of available buffering, and the length of time before buffers may be reused. A switch must gracefully handle the case where a buffered packet\_in message yields no response from the controller. A switch should prevent a buffer from being reused until it has been handled by the controller, or some amount of time (indicated in documentation) has passed.

The total\_len is the full length of the packet that triggered the packet-in message. The actual length of the data field in the message may be less than total\_len in case the packet had been truncated due to buffering.

The reason field indicates which context triggered the packet-in message and can be any of these values:

```
/* Why is this packet being sent to the controller? */
enum ofp_packet_in_reason {
   OFPR_TABLE_MISS = 0, /* No matching flow (table-miss flow entry). */
    OFPR_APPLY_ACTION = 1,
                           /* Output to controller in apply-actions. */
    OFPR_INVALID_TTL = 2,
                           /* Packet has invalid TTL */
    OFPR_ACTION_SET
                     = 3,
                           /* Output to controller in action set. */
    OFPR GROUP
                     = 4,
                           /* Output to controller in group bucket. */
    OFPR_PACKET_OUT = 5,
                            /* Output to controller in packet-out. */
};
```

OFPR\_INVALID\_TTL indicates that a packets with an invalid IP TTL or MPLS TTL was rejected by the OpenFlow pipeline and passed to the controller. Checking for invalid TTL does not need to be done for every packet, but it must be done at a minimum every time a OFPAT\_DEC\_MPLS\_TTL or OFPAT\_DEC\_NW\_TTL action is applied to a packet.

The cookie field contains the cookie of the flow entry that caused the packet to be sent to the controller. This field must be set to -1 (0xfffffffffffff) if a cookie cannot be associated with a particular flow. For example, if the packet-in was generated in a group bucket or from the action set.

The match field is a set of OXM TLVs containing the pipeline fields associated with a packet. The pipeline fields values cannot be determined from the packet data, and include for example the input port and the metadata value (see 7.2.3.9). The OXM TLVs must include the *Packet Type Match Field* to identify the packet type included in the data field, unless the packet is Ethernet (see 7.2.3.11). The set of OXM TLVs must include all pipeline fields associated with that packet, supported by the switch and which value is not all-bits-zero. The field OXM\_OF\_ACTSET\_OUTPUT should be ommitted from this set. If OXM\_OF\_IN\_PHY\_PORT has the same value as OXM\_OF\_IN\_PORT, it should be omitted from this set. The set of OXM TLVs may optionally include pipeline fields which value is all-bits-zero. The set of OXM TLVs may also optionally include packet header fields. Most switches should not include those optional fields, to minimise the size of the packet-in, and therefore the controller should not depend on their presence and should extract header fields from the data field. The set of OXM TLVs must reflect the packet's headers and context when the event that triggers the packet-in message occurred, they should include all modifications made in the course of previous processing.

The port referenced by the OXM\_OF\_IN\_PORT TLV is the packet ingress port used for matching flow entries and must be a valid standard OpenFlow port (see 7.2.3.9). The port referenced by the OXM\_OF\_IN\_PHY\_PORT TLV is the underlying physical port (see 7.2.3.9).

The pad field is additional padding, in addition to the potential padding of the match field, to make sure the IP header of the Ethernet frame is properly aligned. This padding is included even if the data field is empty.

The data field contains part of the packet that triggered the packet-in message, the packet is either included in full in the data field or it is truncated if it is buffered. The packet type is determined by the *Packet Type Match Field* included in the match field, is no Packet Type Match Field is present the packet must be Ethernet (Ethernet frame, including an Ethernet header and Ethernet payload, but no Ethernet FCS - see 7.2.3.11). The packet header reflects any changes applied to the packet in previous processing, but does not include pending changes from the action set.

When a packet is buffered, some number of bytes from the packet beginning will be included in the data field of the message. If the packet is sent because of a "send to controller" action, then this number of bytes must be equal to the max\_len value from the ofp\_action\_output that triggered the message. If the packet is sent for other reasons, such as an invalid TTL, then this number of bytes must be equal to the miss\_send\_len value configured using the OFPT\_SET\_CONFIG message. The default miss\_send\_len is 128 bytes. If the packet is not buffered - either because of no available buffers, or because of being explicitly requested via OFPCML\_NO\_BUFFER - the entire packet must be included in the data field.

#### 7.4.2 Flow Removed Message

If the controller has requested to be notified when flow entries time out or are deleted from tables (see 6.5), the datapath does this with the OFPT\_FLOW\_REMOVED message:

```
/* Flow removed (datapath -> controller). */
struct ofp_flow_removed {
    struct ofp_header header;
```

The match, cookie, and priority fields are the same as those used in the flow mod request.

The reason field is one of the following:

The reason values OFPRR\_IDLE\_TIMEOUT and OFPRR\_HARD\_TIMEOUT are used by the expiry process (see 6.5). The reason value OFPRR\_DELETE is used when the flow entry is removed by a flow-mod request (see 6.4). The reason value OFPRR\_GROUP\_DELETE is used when the flow entry is removed by a group-mod request (see 6.7). The reason value OFPRR\_METER\_DELETE is used when the flow entry is removed by a meter-mod request (see 6.8). The reason value OFPRR\_EVICTION is used when the flow entry is removed by the eviction process (see 6.5).

The stats field contains a list of OXS fields (see 7.2.4.2). The field OXS\_OF\_DURATION is mandatory and track of how long the flow entry has been installed in the switch. The fields OXS\_OF\_PACKET\_COUNT and OXS\_OF\_BYTE\_COUNT are optional and indicate the number of packets and bytes that were associated with this flow entry, respectively.

The idle\_timeout and hard\_timeout fields are directly copied from the flow mod that created this entry. With the above two fields and OXS\_OF\_DURATION, one can find both the amount of time the flow entry was active, as well as the amount of time the flow entry received traffic.

#### 7.4.3 Port Status Message

As ports are added, modified, and removed from the datapath, the controller needs to be informed with the OFPT\_PORT\_STATUS message:

The reason value OFPPR\_ADD denotes a port that did not exist in the datapath and has been added. The reason value OFPPR\_DELETE denotes a port that has been removed from the datapath and no longer exists. The reason value OFPPR\_MODIFY denotes a port which state or config has changed (see 7.2.1).

The desc field is a port description (see 7.2.1). In the port description, all properties don't need to be included, only those properties that have changed must be included, whereas unchanged properties may optionally be included.

# 7.4.4 Controller Role Status Message

When a controller has its role changed by the switch, and not directly changed by that controller using a OFPT\_ROLE\_REQUEST message, the corresponding controller must be informed with a OFPT\_ROLE\_STATUS message. The switch may generate OFPT\_ROLE\_STATUS messages at other times, for example when experimenter data change, this is outside the scope of this specification.

The OFPT\_ROLE\_STATUS message uses the following structure and fields:

```
/* Role status event message. */
struct ofp_role_status {
   struct ofp_header header; /* Type OFPT_ROLE_STATUS. */
                               /* One of OFPCR_ROLE_*. */
   uint32_t role;
                               /* One of OFPCRR_*. */
   uint8_t reason;
   uint8_t pad[3];
                               /* Align to 64 bits. */
    uint64_t generation_id;
                               /* Master Election Generation Id */
    /* Role Property list */
    struct ofp_role_prop_header properties[0];
OFP_ASSERT(sizeof(struct ofp_role_status) == 24);
The reason can be one of the following values:
/* What changed about the controller role */
enum ofp_controller_role_reason {
   OFFCRR_MASTER_REQUEST = 0, /* Another controller asked to be master. */
                     = 1, /* Configuration changed on the switch. */
    OFPCRR_EXPERIMENTER = 2, /* Experimenter data changed. */
};
```

The role is the new role of the controller (see 7.3.8). The generation\_id is the generation ID that was included in the role request message that triggered the role change.

The **properties** field is a list of role properties, describing dynamic parameters of table configuration.

The list of role property types that are currently defined are:

```
/* Role property types.
*/
enum ofp_role_prop_type {
   OFPRPT_EXPERIMENTER
                                 = OxFFFF, /* Experimenter property. */
};
A property definition contains the property type, length, and any associated data:
/* Common header for all Role Properties */
struct ofp_role_prop_header {
   uint16_t
                    type;
                             /* One of OFPRPT_*. */
   uint16_t
                    length; /* Length in bytes of this property. */
OFP_ASSERT(sizeof(struct ofp_role_prop_header) == 4);
The OFPTMPT EXPERIMENTER property uses the following structure and fields:
/* Experimenter role property */
struct ofp_role_prop_experimenter {
   uint16_t
                            /* One of OFPRPT_EXPERIMENTER. */
                    type;
                    length; /* Length in bytes of this property. */
   uint16_t
   uint32_t
                    experimenter; /* Experimenter ID which takes the same
                                       form as in struct
                                       ofp_experimenter_header. */
   uint32_t
                                   /* Experimenter defined. */
                    exp_type;
   /* Followed by:
        - Exactly (length - 12) bytes containing the experimenter data, then
       - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
```

experimenter\_data[0];

OFP\_ASSERT(sizeof(struct ofp\_role\_prop\_experimenter) == 12);

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8).

#### 7.4.5 Table Status Message

ጉ:

When the table state changes, the controller needs to be informed with the OFPT\_TABLE\_STATUS message:

```
/* A table config has changed in the datapath */
struct ofp_table_status {
   struct ofp_header header;
                         /* One of OFPTR_*. */
   uint8_t reason;
   uint8_t pad[7];
                          /* Pad to 64 bits */
    struct ofp_table_desc table; /* New table config. */
OFP_ASSERT(sizeof(struct ofp_table_status) == 24);
The reason can be one of the following values:
/* What changed about the table */
enum ofp_table_reason {
                            /* Vacancy down threshold event. */
   OFPTR_VACANCY_DOWN = 3,
    OFPTR_VACANCY_UP
                     = 4,
                                  /* Vacancy up threshold event. */
};
```

The reason values OFPTR\_VACANCY\_DOWN and OFPTR\_VACANCY\_UP identify a vacancy message. The vacancy events are generated when the remaining space in the flow table changes and crosses one of the vacancy thereshold (see 7.3.4.1), whatever causes the change in remaining space. This change in remaining space can be the result of OpenFlow operations on the table (flow insertion, expiry or removal), or the result of switch internal processing changing the amount of remaining space in the table.

# 7.4.6 Request Forward Message

When a controller modifies the state of groups and meters, the request that successfully modified this state may be forwarded to other controllers. Other controllers are informed with the OFPT REQUESTFORWARD message:

```
/* Group/Meter request forwarding. */
struct ofp_requestforward_header {
    struct ofp_header header; /* Type OFPT_REQUESTFORWARD. */
    struct ofp_header request; /* Request being forwarded. */
};
OFP_ASSERT(sizeof(struct ofp_requestforward_header) == 16);
```

Request forwarding is enabled on a per controller channel basis using the Set Asynchronous Configuration Message (see 7.3.10). The following forwarding reasons may be enabled in the requestforward\_mask field:

# 7.4.7 Controller Status Message

When the status of a controller changes for any of the reasons enumerated below, the switch must send a controller status message to all connected controllers.

Control channel updates are enabled on a per controller channel basis using the Set Asychronous Configuration Messsage (see 7.3.10). The reason code OFPCSR\_REQUEST is used in multipart messages (see 7.3.5.15), and asynchronous messages should not be generated with this reason code. The switch should ignore the asynchronous configuration for this reason code.

The controller status message consists of the OpenFlow header, and a controller status structure representing the current status of the changed controller with reason code. If a single event causes the status of multiple controllers to change (for example, the failure of a network link over which multiple control channels run), the switch must send a different message for each affected controller.

If a controller is removed from the switch's configuration, the switch must send a controller status to all remaining, connected controllers with reason set to OFPCSR\_CONTROLLER\_REMOVED. The controller should ignore the values for role and channel\_status for removed controllers.

The controller status structure is described in 7.2.7.

# 7.5 Symmetric Messages

# 7.5.1 Hello

The OFPT\_HELLO message consists of an OpenFlow header plus a set of variable size hello elements.

```
/* OFPT_HELLO. This message includes zero or more hello elements having
 * variable size. Unknown elements types must be ignored/skipped, to allow
 * for future extensions. */
struct ofp_hello {
    struct ofp_header header;
```

```
/* Hello element list */
   struct ofp_hello_elem_header elements[0]; /* List of elements - 0 or more */
};
OFP_ASSERT(sizeof(struct ofp_hello) == 8);
```

The version field part of the header field (see 7.1.1) must be set to the highest OpenFlow switch protocol version supported by the sender (see 6.3.2).

The elements field is a set of hello elements, containing optional data to inform the initial handshake of the connection. Implementations must ignore (skip) all elements of a Hello message that they do not support. The list of hello elements types that are currently defined are:

```
/* Hello elements types.
enum ofp_hello_elem_type {
    OFPHET_VERSIONBITMAP
                                  = 1, /* Bitmap of version supported. */
};
An element definition contains the element type, length, and any associated data:
/* Common header for all Hello Elements */
struct ofp_hello_elem_header {
                              /* One of OFPHET_*. */
    uint16_t
                     type;
                     length; /* Length in bytes of the element,
    uint16_t
                                 including this header, excluding padding. */
OFP_ASSERT(sizeof(struct ofp_hello_elem_header) == 4);
The OFPHET_VERSIONBITMAP element uses the following structure and fields:
/* Version bitmap Hello Element */
struct ofp_hello_elem_versionbitmap {
                              /* OFPHET_VERSIONBITMAP. */
    uint16_t
                    type;
    uint16_t
                     length; /* Length in bytes of this element,
                                 including this header, excluding padding. */
    /* Followed by:
        - Exactly (length - 4) bytes containing the bitmaps, then
         - Exactly (length + 7)/8*8 - (length) (between 0 and 7)
          bytes of all-zero bytes */
    uint32_t
                    bitmaps[0];
                                  /* List of bitmaps - supported versions */
};
OFP_ASSERT(sizeof(struct ofp_hello_elem_versionbitmap) == 4);
```

The bitmaps field indicates the set of versions of the OpenFlow switch protocol a device supports, and may be used during version negotiation (see 6.3.2). The bits of the set of bitmaps are indexed by the  $ofp\_version$  number of the protocol; if the bit identified by the number of left bitshift equal to a  $ofp\_version$  number is set, this OpenFlow version is supported. The number of bitmaps included in the field depends on the highest version number supported:  $ofp\_versions$  0 to 31 are encoded in the first bitmap,  $ofp\_versions$  32 to 63 are encoded in the second bitmap and so on. For example, if a switch supports only version 1.0 ( $ofp\_version=0x01$ ) and version 1.3 ( $ofp\_version=0x04$ ), the first bitmap would be set to 0x000000012.

#### 7.5.2 Echo Request

An Echo Request message consists of an OpenFlow header plus an arbitrary-length data field. The data field might be a message timestamp to check latency, various lengths to measure bandwidth, or zero-size to verify liveness between the switch and controller.

#### 7.5.3 Echo Reply

An Echo Reply message consists of an OpenFlow header plus the unmodified data field of an echo request message.

In an OpenFlow switch protocol implementation divided into multiple layers, the echo request/reply logic should be implemented in the "deepest" practical layer. For example, in the OpenFlow reference implementation that includes a userspace process that relays to a kernel module, echo request/reply is implemented in the kernel module. Receiving a correctly formatted echo reply then shows a greater likelihood of correct end-to-end functionality than if the echo request/reply were implemented in the userspace process, as well as providing more accurate end-to-end latency timing.

### 7.5.4 Error Message

Error messages are used by the switch or the controller to notify problems to the other side of the connection. They are mostly used by the switch to indicate a failure of a request initiated by the controller. The OFPT\_ERROR\_MSG message use the following structure:

The type value indicates the high-level type of error. The code value is interpreted based on the type. The data is variable in length and interpreted based on the type and code. Unless specified otherwise, the data field must contain at least 64 bytes of the failed message that caused the error message to be generated, if the failed message is shorter than 64 bytes it must contain the full message without any padding.

If the error message is in response to a specific message from the controller, e.g., OFPET\_BAD\_REQUEST, OFPET\_BAD\_ACTION, OFPET\_BAD\_INSTRUCTION, OFPET\_BAD\_MATCH, or OFPET\_FLOW\_MOD\_FAILED, then the xid field of the header must match that of the offending message. If the error is caused by the processing of a request, the error message is sent in place of the reply and the normal reply to the request is not sent.

Error codes ending in \_EPERM correspond to a permissions error generated by, for example, an OpenFlow hypervisor interposing between a controller and switch.

Currently defined error types are:

```
/* Values for 'type' in ofp_error_message. These values are immutable: they
st will not change in future versions of the protocol (although new values may
* be added). */
enum ofp_error_type {
   OFPET_HELLO_FAILED
                             = 0, /* Hello protocol failed. */
   OFPET_BAD_REQUEST
                             = 1, /* Request was not understood. */
   OFPET BAD ACTION
                             = 2, /* Error in action description. */
   OFPET_BAD_INSTRUCTION
                             = 3, /* Error in instruction list. */
   OFPET_BAD_MATCH
                             = 4, /* Error in match. */
   OFPET_FLOW_MOD_FAILED
                             = 5, /* Problem modifying flow entry. */
   OFPET_GROUP_MOD_FAILED = 6, /* Problem modifying group entry. */
   OFPET_PORT_MOD_FAILED
                            = 7, /* Port mod request failed. */
   OFPET_TABLE_MOD_FAILED
                             = 8, /* Table mod request failed. */
   OFPET_QUEUE_OP_FAILED = 9, /* Queue operation failed. */
   OFPET_SWITCH_CONFIG_FAILED = 10, /* Switch config request failed. */
   OFPET_ROLE_REQUEST_FAILED = 11, /* Controller Role request failed. */
                           = 12, /* Error in meter. */
   OFPET_METER_MOD_FAILED
   OFPET_TABLE_FEATURES_FAILED = 13, /* Setting table features failed. */
   OFPET_BAD_PROPERTY
                       = 14, /* Some property is invalid. */
   OFPET_ASYNC_CONFIG_FAILED = 15, /* Asynchronous config request failed. */
   OFPET_FLOW_MONITOR_FAILED = 16, /* Setting flow monitor failed. */
   OFPET_BUNDLE_FAILED = 17, /* Bundle operation failed. */
   OFPET_EXPERIMENTER = Oxffff
                                  /* Experimenter error messages. */
};
```

#### 7.5.4.1 Hello Failed error codes

For the OFPET\_HELLO\_FAILED error type, the following codes are currently defined:

The data field contains an ASCII text string that adds detail on why the error occurred.

If the OpenFlow protocol version negociated via the OFPT\_HELLO message is not supported by the recipient, then the recipient must reply with an OFPT\_ERROR message with a type field of OFPET\_HELLO\_FAILED, a code field of OFPHFC\_INCOMPATIBLE, and optionally an ASCII string explaining the situation in data.

# 7.5.4.2 Bad Request error codes

For the OFPET\_BAD\_REQUEST error type, the following codes are currently defined:

```
/* ofp error msg 'code' values for OFPET BAD REQUEST. 'data' contains at least
* the first 64 bytes of the failed request. */
enum ofp bad request code {
   OFPBRC_BAD_VERSION
                           = 0, /* ofp_header.version not supported. */
                           = 1, /* ofp_header.type not supported. */
   OFPBRC_BAD_TYPE
   OFPBRC_BAD_MULTIPART
                           = 2, /* ofp_multipart_request.type not
                                    supported. */
   OFPBRC_BAD_EXPERIMENTER = 3, /* Experimenter id not supported
                                  * (in ofp_experimenter_header or
                                  * ofp_multipart_request or
                                  * ofp_multipart_reply). */
   OFPBRC_BAD_EXP_TYPE
                          = 4, /* Experimenter type not supported. */
   OFPBRC_EPERM
                           = 5, /* Permissions error. */
                         = 6, /* Wrong request length for type. */
   OFPBRC_BAD_LEN
   OFPBRC_BUFFER_EMPTY = 7, /* Specified buffer has already been used. */
   OFPBRC BUFFER UNKNOWN = 8, /* Specified buffer does not exist. */
   OFPBRC_BAD_TABLE_ID = 9, /* Specified table-id invalid or does not
                                  * exist. */
   OFPBRC_IS_SLAVE
                           = 10, /* Denied because controller is slave. */
   OFPBRC_BAD_PORT
                           = 11, /* Invalid port or missing port. */
   OFPBRC BAD PACKET
                           = 12, /* Invalid packet in packet-out. */
   OFPBRC_MULTIPART_BUFFER_OVERFLOW
                                     = 13, /* ofp_multipart_request
                                    overflowed the assigned buffer. */
   OFPBRC_MULTIPART_REQUEST_TIMEOUT = 14, /* Timeout during multipart
                                              request. */
   OFPBRC_MULTIPART_REPLY_TIMEOUT = 15, /* Timeout during multipart reply. */
   OFPBRC MULTIPART BAD SCHED = 16, /* Switch received a OFPMP BUNDLE FEATURES
                                       request and failed to update the
                                       scheduling tolerance. */
   OFPBRC_PIPELINE_FIELDS_ONLY = 17, /* Match fields must include only
                                        pipeline fields. */
   OFPBRC_UNKNOWN
                           = 18, /* Unspecified error. */
};
```

Error message using the codes OFPBRC\_MULTIPART\_BUFFER\_OVERFLOW, OFPBRC\_MULTIPART\_REQUEST\_TIMEOUT and OFPBRC\_MULTIPART\_REPLY\_TIMEOUT must include an empty data field, and the xid field must match that of the offending multipart message sequence.

If a controller with role set to *Slave* sends to the switch a controller-to-switch commands that send packets or modify the state of the switch, the switch must reply with an OFPT\_ERROR message with a type field of OFPET\_BAD\_REQUEST, a code field of OFPBRC\_IS\_SLAVE.

If the match field in a *Packet-Out* message contains any header fields, the switch must refuse the request and send an ofp\_error\_msg with OFPET\_BAD\_REQUEST type and OFPBRC\_PIPELINE\_FIELDS\_ONLY code.

If an input port is not included in the match field of a *Packet-Out* message, the switch must refuse the request and send an ofp\_error\_msg with OFPET\_BAD\_REQUEST type and OFPBRC\_BAD\_PORT code.

## 7.5.4.3 Bad Action error codes

For the OFPET\_BAD\_ACTION error type, the following codes are currently defined:

```
/* ofp_error_msg 'code' values for OFPET_BAD_ACTION. 'data' contains at least
 * the first 64 bytes of the failed request. */
enum ofp bad action code {
    OFPBAC_BAD_TYPE
                             = 0, /* Unknown or unsupported action type. */
    OFPBAC BAD LEN
                             = 1, /* Length problem in actions. */
    OFPBAC_BAD_EXPERIMENTER = 2, /* Unknown experimenter id specified. */
                             = 3, /* Unknown action for experimenter id. */
    OFPBAC_BAD_EXP_TYPE
    OFPBAC_BAD_OUT_PORT
                             = 4, /* Problem validating output port. */
    OFPBAC_BAD_ARGUMENT
                             = 5, /* Bad action argument. */
    OFPBAC EPERM
                             = 6, /* Permissions error. */
    OFPBAC_TOO_MANY
                             = 7, /* Can't handle this many actions. */
    OFPBAC_BAD_QUEUE
                             = 8, /* Problem validating output queue. */
                             = 9, /* Invalid group id in forward action. */
    OFPBAC_BAD_OUT_GROUP
    OFPBAC_MATCH_INCONSISTENT = 10, /* Action can't apply for this match,
                                      or Set-Field missing prerequisite. */
    OFPBAC UNSUPPORTED ORDER = 11, /* Action order is unsupported for the
                                action list in an Apply-Actions instruction */
    OFPBAC_BAD_TAG
                             = 12, /* Actions uses an unsupported
                                      tag/encap. */
                             = 13, /* Unsupported type in SET_FIELD action. */
    OFPBAC_BAD_SET_TYPE
    OFPBAC_BAD_SET_LEN
                             = 14, /* Length problem in SET_FIELD action. */
    OFPBAC_BAD_SET_ARGUMENT = 15, /* Bad argument in SET_FIELD action. */
    OFPBAC_BAD_SET_MASK
                             = 16, /* Bad mask in SET_FIELD action. */
};
```

If a message specifies an action that is invalid or not supported in the specified context (table, group, packet-out), the switch must return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_BAD\_TYPE code.

If a set of actions included in a *Write-Actions* instruction contains more than one instance of an action type or set-field action type, the switch may optionally return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_TOO\_MANY code.

If a list of actions included in a *Apply-Actions* instruction contains more actions than the switch supports, then the switch must return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_TOO\_MANY code.

If a list of actions contains a sequence of actions that the switch can not support in the specified order, the switch must return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_UNSUPPORTED\_ORDER code.

If any action references a port that will never be valid on a switch, the switch must return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_BAD\_OUT\_PORT code. If the referenced port may be valid in the future, e.g. when a linecard is added to a chassis switch, or a port is dynamically added to a software switch, the switch must either silently drop packets sent to the referenced port, or immediately return an OFPBAC\_BAD\_OUT\_PORT error and refuse the flow mod.

If an *action* in a message references a group that is not currently defined on the switch, or is a reserved group, such as OFPG\_ALL, the switch must return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_BAD\_OUT\_GROUP code.

If an *action* in a message has a value that is invalid, for example a Push action with an invalid Ethertype, and this situation is not covered by another error codes (such as *bad output port*, *bad group id* or *bad set argument*), the switch must return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_BAD\_ARGUMENT code.

If an action in a message performs an operation which is inconsistent with the match and prior actions of the same message, for example, a  $pop\ VLAN$  action with a match specifying no VLAN, or a  $set\ TTL$  action with a match wildcarding the Ethertype, the switch may optionally reject the flow mod and immediately return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_MATCH\_INCONSISTENT code.

If a *set-field* action in a message has a value that is invalid, for example a set-field action for OXM VLAN\_VID with value greater than 4095, or a DSCP value using more than 6 bits, the switch must return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_BAD\_SET\_ARGUMENT code.

If a set-field action in a flow mod message does not have its prerequisites included in the match or prior actions in the same message, for example, a set IPv4 address action with a match wildcarding the Ethertype, the switch must reject the flow mod and immediately return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_MATCH\_INCONSISTENT code. The effect of any inconsistent actions on matched packets is undefined. Controllers are strongly encouraged to avoid generating combinations of table entries that may yield inconsistent actions.

If a *set-field* action or *Copy-Field* action specifies a field or a class that is not supported in the specified table, the switch must return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_BAD\_SET\_TYPE code.

If a Set-Field action includes an OXM mask (oxm\_hasmask field set), and the switch does not support masking for this OXM type, the switch must reject the flow mod and immediately return an ofp error msg with OFPET BAD ACTION type and OFPBMC BAD SET MASK code.

If the OXM field in a *Set-Field* action includes a mask, if for a 0-bit in oxm\_mask the corresponding bit in oxm\_value is a 1-bit, the switch must return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_BAD\_SET\_MASK code.

If a *Copy-Field* action specifies invalid offsets, the switch must return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_BAD\_SET\_ARGUMENT code.

If a *Copy-Field* action specifies overlapping source and destination and the switch does not support such operation, the switch must return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_BAD\_SET\_TYPE code.

# 7.5.4.4 Bad Instruction error codes

For the OFPET\_BAD\_INSTRUCTION error type, the following codes are currently defined:

If the instructions included in a message are unknown, the switch must return an ofp\_error\_msg with OFPET\_BAD\_INSTRUCTION type and OFPBIC\_UNKNOWN\_INST code.

If the instructions included in a message are unsupported the switch must return an ofp\_error\_msg with OFPET\_BAD\_INSTRUCTION type and OFPBIC\_UNSUP\_INST code.

If the instructions included in a set of instructions in a message contain two or more instructions with the same type, the switch must return an ofp\_error\_msg with OFPET\_BAD\_INSTRUCTION type and OFPBIC\_DUP\_INST code.

If the instructions included in a message contain a *Goto-Table* and the next-table-id refers to an invalid table the switch must return an ofp\_error\_msg with OFPET\_BAD\_INSTRUCTION type and OFPBIC\_BAD\_TABLE\_ID code.

If the instructions requested contain a *Write-Metadata* and the metadata value or metadata mask value is unsupported then the switch must return an ofp\_error\_msg with OFPET\_BAD\_INSTRUCTION type and OFPBIC\_UNSUP\_METADATA or OFPBIC\_UNSUP\_METADATA\_MASK code.

If a *Clear-Actions* instruction contains some actions, the switch must return an ofp\_error\_msg with OFPET\_BAD\_INSTRUCTION type and OFPBIC\_BAD\_LEN code.

## 7.5.4.5 Bad Match error codes

For the OFPET\_BAD\_MATCH error type, the following codes are currently defined:

```
does not support arbitrary network
                                    address mask. */
   OFPBMC_BAD_WILDCARDS
                           = 5, /* Unsupported combination of fields masked
                                    or omitted in the match. */
                           = 6, /* Unsupported field type in the match. */
   OFPBMC_BAD_FIELD
   OFPBMC_BAD_VALUE
                           = 7, /* Unsupported value in a match field. */
   OFPBMC_BAD_MASK
                           = 8, /* Unsupported mask specified in the match. */
   OFPBMC_BAD_PREREQ
                           = 9, /* A prerequisite was not met. */
   OFPBMC_DUP_FIELD
                           = 10, /* A field type was duplicated. */
   OFPBMC_EPERM
                           = 11, /* Permissions error. */
};
```

If the match in a message specifies a field or a class that is not supported in the specified table, the switch must return an ofp\_error\_msg with OFPET\_BAD\_MATCH type and OFPBMC\_BAD\_FIELD code.

If the match in a message specifies a field more than once, the switch must return an ofp\_error\_msg with OFPET\_BAD\_MATCH type and OFPBMC\_DUP\_FIELD code.

If the match in a message specifies a field but fail to specify its associated prerequisites (see 7.2.3.6), for example specifies an IPv4 address without matching the EtherType to 0x800, the switch must return an ofp\_error\_msg with OFPET\_BAD\_MATCH type and OFPBMC\_BAD\_PREREQ code.

If the match in a message specifies an arbitrary bitmask for either the datalink or network addresses which the switch cannot support, the switch must return an ofp\_error\_msg with OFPET\_BAD\_MATCH type and either OFPBMC\_BAD\_DL\_ADDR\_MASK or OFPBMC\_BAD\_NW\_ADDR\_MASK. If the bitmasks specified in both the datalink and network addresses are not supported then OFPBMC\_BAD\_DL\_ADDR\_MASK should be used. If the match in a message specifies an arbitrary bitmask for another field which the switch cannot support, the switch must return an ofp\_error\_msg with OFPET\_BAD\_MATCH type and OFPBMC\_BAD\_MASK code.

If the match in a message specifies values that cannot be matched, for example, a VLAN ID greater than 4095 and not one of the reserved values, or a DSCP value using more than 6 bits, the switch must return an ofp\_error\_msg with OFPET\_BAD\_MATCH type and OFPBMC\_BAD\_VALUE code.

If an OXM field in the match includes a mask, if for a 0-bit in oxm\_mask the corresponding bit in oxm\_value is a 1-bit, the switch must return an ofp\_error\_msg with OFPET\_BAD\_MATCH type and OFPBMC\_BAD\_WILDCARDS code.

If a two OXM fields in the match have the same type, the switch should return an ofp\_error\_msg with OFPET\_BAD\_MATCH type and OFPBMC\_DUP\_FIELD code.

# 7.5.4.6 Flow-mod Failed error codes

For the OFPET\_FLOW\_MOD\_FAILED error type, the following codes are currently defined:

```
/* ofp_error_msg 'code' values for OFPET_FLOW_MOD_FAILED. 'data' contains
 * at least the first 64 bytes of the failed request. */
enum ofp_flow_mod_failed_code {
    OFPFMFC_UNKNOWN = 0, /* Unspecified error. */
    OFPFMFC_TABLE_FULL = 1, /* Flow not added because table was full. */
    OFPFMFC_BAD_TABLE_ID = 2, /* Table does not exist */
    OFPFMFC_OVERLAP = 3, /* Attempted to add overlapping flow with
```

```
CHECK_OVERLAP flag set. */
    OFPFMFC EPERM
                        = 4, /* Permissions error. */
    OFPFMFC_BAD_TIMEOUT = 5,
                               /* Flow not added because of unsupported
                                  idle/hard timeout. */
                               /* Unsupported or unknown command. */
    OFPFMFC_BAD_COMMAND = 6,
    OFPFMFC_BAD_FLAGS
                        = 7,
                               /* Unsupported or unknown flags. */
    OFPFMFC_CANT_SYNC
                        = 8,
                              /* Problem in table synchronisation. */
                              /* Unsupported priority value. */
    OFPFMFC_BAD_PRIORITY = 9,
    OFPFMFC_IS_SYNC
                        = 10, /* Synchronised flow entry is read only. */
};
```

If a switch cannot find any space in the requested table in which to add the flow entry in a *Flow-Mod* message, the switch must send an ofp\_error\_msg with OFPET\_FLOW\_MOD\_FAILED type and OFPFMFC\_TABLE\_FULL code.

If the flow modification message specifies an invalid table-id, the switch must send an <code>ofp\_error\_msg</code> with <code>OFPET\_FLOW\_MOD\_FAILED</code> type and <code>OFPFMFC\_BAD\_TABLE\_ID</code> code. If the flow modification message specifies <code>OFPTT\_ALL</code> for table-id in a <code>add</code> or <code>modify</code> request, the switch must send the same error message.

If a Flow-Mod message with an add request has the OFPFF\_CHECK\_OVERLAP flag set and the request has an overlap conflict (see 6.4), the switch must reply with an ofp\_error\_msg with OFPET\_FLOW\_MOD\_FAILED type and OFPFMFC OVERLAP code.

If a flow entry is added or modified in a source flow table, and if another flow table is sychronised on that source flow table and the switch can't synchronise a flow mod request, the switch must reject the flow mod and immediately return an ofp\_error\_msg with OFPET\_FLOW\_MOD\_FAILED type and OFPFMFC\_CANT\_SYNC code.

If a flow entry is added in a source flow table with the OFPFF\_CHECK\_OVERLAP flag set, and if another flow table is sychronised on that source flow table and the corresponding flow entry would overlap a flow entry already residing in the synchronised flow table, the switch must refuse the full flow-mod request and respond with an ofp\_error\_msg with OFPET\_FLOW\_MOD\_FAILED type and OFPFMFC\_CANT\_SYNC code.

If the controller attempt to add, modify or delete a flow entry in a synchronised flow table and the switch can't support such changes, the switch must reject the flow mod and immediately return an ofp\_error\_msg with OFPET\_FLOW\_MOD\_FAILED type and OFPFMFC\_IS\_SYNC code.

If any error which can not be mapped to an existing error code occurs during the processing of the flow mod message, the switch may return an ofp\_error\_msg with OFPET\_FLOW\_MOD\_FAILED type and OFPFMC\_UNKNOWN code.

#### 7.5.4.7 Group-mod Failed error codes

For the OFPET GROUP MOD FAILED error type, the following codes are currently defined:

```
already-present group. */
                                 = 1, /* Group not added because Group
    OFPGMFC_INVALID_GROUP
                                         specified is invalid. */
    OFPGMFC_WEIGHT_UNSUPPORTED
                                = 2, /* Switch does not support unequal load
                                         sharing with select groups. */
                                = 3, /* The group table is full. */
    OFPGMFC_OUT_OF_GROUPS
    OFPGMFC_OUT_OF_BUCKETS
                                 = 4, /* The maximum number of action buckets
                                         for a group has been exceeded. */
    OFPGMFC_CHAINING_UNSUPPORTED = 5, /* Switch does not support groups that
                                         forward to groups. */
    OFPGMFC_WATCH_UNSUPPORTED
                                = 6, /* This group cannot watch the watch_port
                                         or watch_group specified. */
    OFPGMFC_LOOP
                                 = 7, /* Group entry would cause a loop. */
    OFPGMFC_UNKNOWN_GROUP
                                = 8, /* Group not modified because a group
                                         MODIFY attempted to modify a
                                         non-existent group. */
    OFPGMFC_CHAINED_GROUP
                                = 9, /* Group not deleted because another
                                          group is forwarding to it. */
    OFPGMFC_BAD_TYPE
                                = 10, /* Unsupported or unknown group type. */
    OFPGMFC_BAD_COMMAND
                                = 11, /* Unsupported or unknown command. */
    OFPGMFC_BAD_BUCKET
                                = 12, /* Error in bucket. */
                                = 13, /* Error in watch port/group. */
    OFPGMFC_BAD_WATCH
    OFPGMFC_EPERM
                                = 14, /* Permissions error. */
                           = 15, /* Invalid bucket identifier used in
    OFPGMFC_UNKNOWN_BUCKET
                                          INSERT BUCKET or REMOVE BUCKET
                                          command. */
    OFPGMFC_BUCKET_EXISTS
                                = 16, /* Can't insert bucket because a bucket
                                         already exist with that bucket-id. */
};
```

If a Group-Mod request with command **add** specifies a group identifier that already resides in the group table, then the switch must refuse to add the group entry and must send an <code>ofp\_error\_msg</code> with <code>OFPET\_GROUP\_MOD\_FAILED</code> type and <code>OFPGMFC\_GROUP\_EXISTS</code> code.

If a Group-Mod request with command **modify** or **insert bucket** specifies a group identifier that does not already exist, then the switch must refuse the group mod and send an ofp\_error\_msg with OFPET\_GROUP\_MOD\_FAILED type and OFPGMFC\_UNKNOWN\_GROUP code.

If a specified group type is invalid or not supported by the switch, then the switch must refuse to add the group entry and must send an ofp\_error\_msg with OFPET\_GROUP\_MOD\_FAILED type and OFPGMFC\_BAD\_TYPE code.

If the group-mod request specifies more than one bucket for a group of type *Indirect*, the switch must refuse to add the group entry and must send an ofp\_error\_msg with OFPET\_GROUP\_MOD\_FAILED type and OFPGMFC\_INVALID\_GROUP code.

If a specified group is invalid (ie: specifies a non-zero weight for a group which type is not select) then the switch must refuse to add the group entry and must send an ofp\_error\_msg with OFPET\_GROUP\_MOD\_FAILED type and OFPGMFC\_INVALID\_GROUP code.

If a switch does not support unequal load sharing with select groups (buckets with weight different than 1), it must refuse to add the group entry and must send an ofp\_error\_msg with OFPET\_GROUP\_MOD\_FAILED type and OFPGMFC\_WEIGHT\_UNSUPPORTED code.

If a switch cannot add the incoming group entry due to lack of space, the switch must send an ofp\_error\_msg with OFPET\_GROUP\_MOD\_FAILED type and OFPGMFC\_OUT\_OF\_GROUPS code.

If a switch cannot add the incoming group entry due to restrictions (hardware or otherwise) limiting the number of group buckets, it must refuse to add the group entry and must send an ofp\_error\_msg with OFPET\_GROUP\_MOD\_FAILED type and OFPGMFC\_OUT\_OF\_BUCKETS code.

If a switch cannot add the incoming group because it does not support the proposed liveliness configuration, the switch must send an ofp\_error\_msg with OFPET\_GROUP\_MOD\_FAILED type and OFPGMFC\_WATCH\_UNSUPPORTED code. This includes specifying watch\_port or watch\_group for a group that does not support liveness, or specifying a port that does not support liveness in watch\_port, or specifying a group that does not support liveness in watch\_group.

For Group-Mod requests with command **insert bucket** or **remove bucket**, if the <code>command\_bucket\_id</code> field value does not already exist in the specified group or is not one of the reserved values for that command, then the switch must refuse the group mod and send an <code>ofp\_error\_msg</code> with <code>OFPET\_GROUP\_MOD\_FAILED</code> type and <code>OFPGMFC\_UNKNOWN\_BUCKET</code> code.

For Group-Mod requests with command **remove bucket**, if the current action bucket list is empty, the switch must refuse the group mod and send an ofp\_error\_msg with OFPET\_GROUP\_MOD\_FAILED type and OFPGMFC\_UNKNOWN\_BUCKET code.

For Group-Mod requests with command **insert bucket**, if a groups request would make the group have a duplicate Bucket ID, the switch must refuse the group mod and send an ofp\_error\_msg with OFPET\_GROUP\_MOD\_FAILED type and OFPGMFC\_BUCKET\_EXISTS code.

If a switch does not support group chaining or groups referencing groups, it must send an ofp\_error\_msg with OFPET\_GROUP\_MOD\_FAILED type and OFPGMFC\_CHAINING\_UNSUPPORTED code.

If an action in a bucket references a group that is not currently defined on the switch, or is a reserved group, such as OFPG\_ALL, the switch must return an ofp\_error\_msg with OFPET\_BAD\_ACTION type and OFPBAC\_BAD\_OUT\_GROUP code.

If a switch supports group chaining and checking for loops, and if the group-mod would create a forwarding loop, the switch must reject the group mod and must send an ofp\_error\_msg with OFPET\_GROUP\_MOD\_FAILED type and OFPGMFC\_LOOP code.

If a switch supports group chaining and checking that chained groups are not removed, and if the group-mod would delete a group referenced by another group, the switch must refuse to delete the group entry and must send an <code>ofp\_error\_msg</code> with <code>OFPET\_GROUP\_MOD\_FAILED</code> type and <code>OFPGMFC\_CHAINED\_GROUP</code> code.

## 7.5.4.8 Port-mod Failed error codes

For the OFPET\_PORT\_MOD\_FAILED error type, the following codes are currently defined:

```
/* ofp_error_msg 'code' values for OFPET_PORT_MOD_FAILED. 'data' contains
 * at least the first 64 bytes of the failed request. */
enum ofp_port_mod_failed_code {
    OFPPMFC_BAD_PORT = 0,    /* Specified port number does not exist. */
    OFPPMFC_BAD_HW_ADDR = 1,    /* Specified hardware address does not
```

```
* match the port number. */

OFPPMFC_BAD_CONFIG = 2, /* Specified config is invalid. */

OFPPMFC_BAD_ADVERTISE = 3, /* Specified advertise is invalid. */

OFPPMFC_EPERM = 4, /* Permissions error. */

};
```

#### 7.5.4.9 Table-mod Failed error codes

For the OFPET\_TABLE\_MOD\_FAILED error type, the following codes are currently defined:

## 7.5.4.10 Queue-op Failed error codes

For the OFPET\_QUEUE\_OP\_FAILED error type, the following codes are currently defined:

# 7.5.4.11 Switch Config Failed error codes

For the OFPET\_SWITCH\_CONFIG\_FAILED error type, the following codes are currently defined:

```
/* ofp_error_msg 'code' values for OFPET_SWITCH_CONFIG_FAILED. 'data' contains
 * at least the first 64 bytes of the failed request. */
enum ofp_switch_config_failed_code {
    OFPSCFC_BAD_FLAGS = 0, /* Specified flags is invalid. */
    OFPSCFC_BAD_LEN = 1, /* Specified miss send len is invalid. */
    OFPSCFC_EPERM = 2, /* Permissions error. */
};
```

### 7.5.4.12 Role Request Failed error codes

For the OFPET\_ROLE\_REQUEST\_FAILED error type, the following codes are currently defined:

If the switch receives a OFPT\_ROLE\_REQUEST with role equal to OFPCR\_ROLE\_MASTER or OFPCR\_ROLE\_SLAVE and with a generation\_id smaller than a previously seen generation id, switch must reply with an error message with type OFPET\_ROLE\_REQUEST\_FAILED and code OFPRRFC\_STALE.

#### 7.5.4.13 Meter-mod Failed error codes

For the OFPET METER MOD FAILED error type, the following codes are currently defined:

```
/* ofp_error_msg 'code' values for OFPET_METER_MOD_FAILED. 'data' contains
 * at least the first 64 bytes of the failed request. */
enum ofp_meter_mod_failed_code {
    OFPMMFC_UNKNOWN
                      = 0, /* Unspecified error. */
    OFPMMFC_METER_EXISTS = 1, /* Meter not added because a Meter ADD
                                  * attempted to replace an existing Meter. */
    OFPMMFC_INVALID_METER = 2, /* Meter not added because Meter specified
                                   * is invalid,
                                   * or invalid meter in meter action. */
    OFPMMFC_UNKNOWN_METER = 3, /* Meter not modified because a Meter MODIFY
                                   * attempted to modify a non-existent Meter,
                                   * or bad meter in meter action. */
    OFPMMFC_BAD_COMMAND = 4, /* Unsupported or unknown command. */
    OFPMMFC_BAD_FLAGS = 5, /* Flag configuration unsupported. */
OFPMMFC_BAD_RATE = 6, /* Rate unsupported. */
    OFPMMFC_BAD_BURST = 7, /* Burst size unsupport
OFPMMFC_BAD_BAND = 8, /* Band unsupported. */
                           = 7, /* Burst size unsupported. */
    OFPMMFC_BAD_BAND_VALUE = 9, /* Band value unsupported. */
    OFPMMFC_OUT_OF_METERS = 10, /* No more meters available. */
    OFPMMFC_OUT_OF_BANDS = 11, /* The maximum number of properties
                                   * for a meter has been exceeded. */
};
```

If an *action* in a message references a meter that is not currently defined on the switch, the switch must return an ofp\_error\_msg with OFPET\_METER\_MOD\_FAILED type and OFPMMFC\_UNKNOWN\_METER code.

If a Meter-Mod request with command **add** specifies a meter identifier that already exist, then the switch must refuse to add the meter and must send an ofp\_error\_msg with OFPET\_METER\_MOD\_FAILED type and OFPMMFC\_METER\_EXISTS code.

If a Meter-Mod request with command **modify** specifies a meter identifier that does not already exist, then the switch must refuse the meter mod and send an ofp\_error\_msg with OFPET\_METER\_MOD\_FAILED type and OFPMMFC\_UNKNOWN\_METER code.

If a switch cannot add or modify the incoming meter entry due to lack of space, the switch must send an ofp\_error\_msg with OFPET\_METER\_MOD\_FAILED type and OFPMMFC\_OUT\_OF\_METERS code.

If a switch cannot add or modify the incoming meter entry due to restrictions (hardware or otherwise) limiting the number of bands, it must refuse to add the meter entry and must send an <code>ofp\_error\_msg</code> with <code>OFPET\_METER\_MOD\_FAILED</code> type and <code>OFPMMFC\_OUT\_OF\_BANDS</code> code.

#### 7.5.4.14 Table-features Failed error codes

For the OFPET\_TABLE\_FEATURES\_FAILED error type, the following codes are currently defined:

If the switch is unable to set the requested configuration from the table feature request in its entirety, an error of type OFPET\_TABLE\_FEATURES\_FAILED is returned with the appropriate error code.

If a switch does not support the requested table features request command, an error of type OFPET\_TABLE\_FEATURES\_FAILED and code OFPTFFC\_BAD\_COMMAND is returned.

For commands other than OFPTFC\_REPLACE, if the number of flow tables is greater than the switch supports, an error of type OFPET\_TABLE\_FEATURES\_FAILED and code OFPTFFC\_TOO\_MANY is returned.

# 7.5.4.15 Bad Property error codes

For the OFPET\_BAD\_PROPERTY error type, the following codes are currently defined:

```
/* ofp_error_msg 'code' values for OFPET_BAD_PROPERTY. 'data' contains at least
* the first 64 bytes of the failed request. */
enum ofp_bad_property_code {
   OFPBPC BAD TYPE
                             = 0, /* Unknown or unsupported property type. */
   OFPBPC_BAD_LEN
                             = 1, /* Length problem in property. */
   OFPBPC_BAD_VALUE
                            = 2, /* Unsupported property value. */
   OFPBPC_TOO_MANY
                             = 3, /* Can't handle this many properties. */
   OFPBPC_DUP_TYPE
                             = 4, /* A property type was duplicated. */
   OFPBPC BAD EXPERIMENTER = 5, /* Unknown experimenter id specified. */
   OFPBPC_BAD_EXP_TYPE
                             = 6, /* Unknown exp_type for experimenter id. */
```

```
OFPBPC_BAD_EXP_VALUE = 7, /* Unknown value for experimenter id. */
OFPBPC_EPERM = 8, /* Permissions error. */
};
```

# 7.5.4.16 Async Config Failed error codes

For the OFPET\_ASYNC\_CONFIG\_FAILED error type, the following codes are currently defined:

#### 7.5.4.17 Flow-monitor Failed error codes

For the OFPET\_FLOW\_MONITOR\_FAILED error type, the following codes are currently defined:

```
/* ofp_error_msg 'code' values for OFPET_FLOW_MONITOR_FAILED. 'data' contains
 * at least the first 64 bytes of the failed request. */
enum ofp_flow_monitor_failed_code {
    OFPMOFC_UNKNOWN
                       = 0, /* Unspecified error. */
    OFPMOFC_MONITOR_EXISTS = 1, /* Monitor not added because a Monitor ADD
                               * attempted to replace an existing Monitor. */
    OFPMOFC_INVALID_MONITOR = 2, /* Monitor not added because Monitor specified
                                * is invalid. */
    OFPMOFC_UNKNOWN_MONITOR = 3, /* Monitor not modified because a Monitor
                                  MODIFY attempted to modify a non-existent
                                  Monitor. */
    OFPMOFC_BAD_COMMAND = 4, /* Unsupported or unknown command. */
    OFPMOFC_BAD_FLAGS = 5, /* Flag configuration unsupported. */
    OFPMOFC_BAD_TABLE_ID = 6, /* Specified table does not exist. */
    OFPMOFC_BAD_OUT = 7, /* Error in output port/group. */
};
```

#### 7.5.4.18 Bundle Failed error codes

For the OFPET\_BUNDLE\_FAILED error type, the following codes are currently defined:

```
OFPBFC_BAD_TYPE
                       = 6, /* Unsupported or unknown message control type. */
 OFPBFC_BAD_FLAGS
                        = 7, /* Unsupported, unknown, or inconsistent flags. */
 OFPBFC_MSG_BAD_LEN
                       = 8, /* Length problem in included message. */
                       = 9, /* Inconsistent or duplicate XID. */
 OFPBFC_MSG_BAD_XID
 OFPBFC_MSG_UNSUP
                       = 10, /* Unsupported message in this bundle. */
  OFPBFC_MSG_CONFLICT
                       = 11, /* Unsupported message combination in this
                                bundle. */
 OFPBFC_MSG_TOO_MANY
                       = 12, /* Can't handle this many messages in bundle. */
 OFPBFC_MSG_FAILED
                       = 13, /* One message in bundle failed. */
 OFPBFC_TIMEOUT
                        = 14, /* Bundle is taking too long. */
 OFPBFC_BUNDLE_IN_PROGRESS = 15, /* Bundle is locking the resource. */
 OFPBFC_SCHED_NOT_SUPPORTED = 16, /* Scheduled commit was received and
                                     scheduling is not supported. */
 OFPBFC_SCHED_FUTURE = 17, /* Scheduled commit time exceeds upper bound. */
 OFPBFC_SCHED_PAST = 18,
                             /* Scheduled commit time exceeds lower bound. */
};
```

If the bundle\_id in a Bundle Open Request refers to an existing bundle attached to the same connection, the switch must refuse to open the new bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_ID code. The existing bundle identified by bundle\_id must be discarded.

If the switch can not open the bundle specified in a *Bundle Open Request* because its having too many opened bundles on the switch or attached to the current connection, the switch must refuse to open the new bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_OUT\_OF\_BUNDLES code.

If the switch can not open the bundle specified in a *Bundle Open Request* because the connection is using an unreliable transport, the switch must refuse to open the new bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_OUT\_OF\_BUNDLES code.

If the flags field specified in a *Bundle Request* specifies some feature that can not be implemented by the switch, the switch must refuse to open the new bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_FLAGS code.

If the bundle\_id in a *Bundle Add Request* a refers to a bundle that is already closed, the switch must refuse to add the message to the bundle, discard the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BUNDLE\_CLOSED code.

If the flags field in a Bundle Add Request, Bundle Close Request or Bundle Commit Request is different from the flags that were specified when the bundle was opened, the switch must refuse to add the message to the bundle, discard the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_FLAGS code.

If the message in a *Bundle Add Request* is normally supported on the switch but is not supported in a bundle, the switch must refuse to add the message to the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_MSG\_UNSUP code. This is the case for hello, echo, and bundle messages, messages that are not requests (for example replies, status and errors messages), or if the implementation does not support including a specific modification message in a bundle.

If the message in a *Bundle Add Request* is incompatible with another message already stored in the bundle, the switch must refuse to add the message to the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_MSG\_CONFLICT code.

If the bundle is full and can not fit the message in the *Bundle Add Request*, the switch must refuse to add the message to the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_MSG\_TOO\_MANY code.

If the message in the *Bundle Add Request* does not have a valid length field, the switch must refuse to add the message to the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_MSG\_BAD\_LEN code.

If the bundle\_id in a Bundle Close Request or Bundle Commit Request refers to a bundle that does not exist, the switch must reject the request and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BAD\_ID code.

If the bundle\_id in a *Bundle Close Request* refers to a bundle that is already closed, the switch must refuse to close to the bundle, discard the bundle and send an ofp\_error\_msg with OFPET\_BUNDLE\_FAILED type and OFPBFC\_BUNDLE\_CLOSED code.

# 7.5.4.19 Experimenter Error Message

For the OFPET\_EXPERIMENTER error type, the error message is defined by the following structure and fields:

The experimenter field is the Experimenter ID, which takes the same form as in the typical experimenter structure (see 7.2.8). The exp\_code field is the experimenter code, a 16 bit field managed by the experimenter and it can have any value and function the experimenter wishes. The data field is experimenter defined and does not need to be padded.

#### 7.5.5 Experimenter Message

The Experimenter message is defined as follows:

```
/* Experimenter-defined arbitrary additional data. */
    uint8_t experimenter_data[0];
};
OFP_ASSERT(sizeof(struct ofp_experimenter_msg) == 16);
```

The experimenter field and identifies the experimenter, the exp\_type field is the experimenter type, and experimenter\_data is the exprimenter arbitrary data. They take the same form as in the typical experimenter structure (see 7.2.8). The Experimenter message does not need to be padded.

As opposed to other Experimenter extensions, Experimenter messages are not associated with a specific OpenFlow object, and therefore can be used to create entirely new APIs and manage entirely new objects.

If a switch does not understand an experimenter message, it must send an OFPT\_ERROR message with a OFPBRC\_BAD\_EXPERIMENTER error code and OFPET\_BAD\_REQUEST error type.

/* Define for compatibility */
                            OFPVID NONE
#define OFP_VLAN_NONE
/* 802.1Q VID.
 * For a packet with an 802.1Q header, this is the VLAN-ID (VID) from the
 \boldsymbol{\ast} outermost tag, with the CFI bit forced to 1. For a packet with no 802.1Q
 * header, this has value OFPVID_NONE.
 * Prereas: None.
 * Format: 16-bit integer in network byte order with bit 13 indicating
 * presence of VLAN header and 3 most-significant bits forced to 0.
 * Only the lower 13 bits have meaning.
 * Masking: Arbitrary masks.
 * This field can be used in various ways:
   - If it is not constrained at all, the nx_match matches packets without
       an 802.1Q header or with an 802.1Q header that has any VID value.
    - Testing for an exact match with 0x0 matches only packets without
       an 802.1Q header.
    - Testing for an exact match with a VID value with CFI=1 matches packets
       that have an 802.1Q header with a specified VID.
   - Testing for an exact match with a nonzero VID value with CFI=O does
       not make sense. The switch may reject this combination.
   - Testing with nxm_value=0, nxm_mask=0x0fff matches packets with no 802.1Q
      header or with an 802.10 header with a VID of 0.
   - Testing with nxm_value=0x1000, nxm_mask=0x1000 matches packets with an 802.1Q header that has any VID value.

/* Configures the "role" of the sending controller. The default role is:
      - Equal (OFPCR_ROLE_EQUAL), which allows the controller access to all
        OpenFlow features. All controllers have equal responsibility.
 * The other possible roles are a related pair:
      - Master (OFPCR_ROLE_MASTER) is equivalent to Equal, except that there
        may be at most one Master controller at a time: when a controller
        configures itself as Master, any existing Master is demoted to the
        Slave role.
      - Slave (OFPCR_ROLE_SLAVE) allows the controller read-only access to
        OpenFlow features. In particular attempts to modify the flow table
        will be rejected with an OFPBRC_EPERM error.
        Slave controllers do not receive OFPT_PACKET_IN or OFPT_FLOW_REMOVED
        messages, but they do receive OFPT_PORT_STATUS messages.
 * Also configures the ID for the controller. The default ID is
* OFPCID_UNDEFINED, and controllers may set the short_id to change their ID.
 * Only the OFPCID_UNDEFINED ID may be assigned to more than one controller,
 * and setting the short_id to a value in use will be rejected.

# Appendix B Release Notes

This section contains release notes highlighting the main changes between the main versions of the OpenFlow protocol.

The text of the release notes is informative and historical, and should not be considered normative. Many items of the release notes refer to features and text that has been removed, replaced or updated in subsequent versions of this specification, and therefore do not necessarily match the actual specification.

# B.1 OpenFlow version 0.2.0

Release date: March 28,2008

Protocol version: 1

# B.2 OpenFlow version 0.2.1

Release date: March 28,2008

Protocol version: 1 No protocol change.

# B.3 OpenFlow version 0.8.0

Release date: May 5, 2008 Protocol version: 0x83

- Reorganise OpenFlow message types
- Add OFPP\_TABLE virtual port to send packet-out packet to the tables
- Add global flag OFPC\_SEND\_FLOW\_EXP to configure flow expired messages generation
- Add flow priority
- Remove flow Group-ID (experimental QoS support)
- Add Error messages
- Make stat request and stat reply more generic, with a generic header and stat specific body
- Change fragmentation strategy for stats reply, use explicit flag OFPSF\_REPLY\_MORE instead of empty packet
- Add table stats and port stats mesages

# B.4 OpenFlow version 0.8.1

Release date: May 20, 2008 Protocol version: 0x83 No protocol change.

# B.5 OpenFlow version 0.8.2

Release date: October 17, 2008

Protocol version: 0x85

- Add Echo Request and Echo Reply messages
- Make all message 64 bits aligned

# B.6 OpenFlow version 0.8.9

Release date: December 2, 2008

Protocol version: 0x97

#### **B.6.1** IP Netmasks

It is now possible for flow entries to contain IP subnet masks. This is done by changes to the wildcards field, which has been expanded to 32-bits:

```
/* Flow wildcards. */
enum ofp_flow_wildcards {
OFPFW_IN_PORT = 1 << 0, /* Switch input port. */
OFPFW_DL_VLAN = 1 << 1, /* VLAN. */
OFPFW_DL_SRC
             = 1 << 2, /* Ethernet source address. */
OFPFW_DL_DST = 1 << 3, /* Ethernet destination address. */
OFPFW_DL_TYPE = 1 << 4, /* Ethernet frame type. */
OFPFW_NW_PROTO = 1 << 5, /* IP protocol. */
OFPFW_TP_SRC = 1 << 6, /* TCP/UDP source port. */
            = 1 << 7, /* TCP/UDP destination port. */
OFPFW TP DST
/* IP source address wildcard bit count. O is exact match, 1 ignores the
* LSB, 2 ignores the 2 least-significant bits, ..., 32 and higher wildcard
* the entire field. This is the *opposite* of the usual convention where
 * e.g. /24 indicates that 8 bits (not 24 bits) are wildcarded. */
OFPFW_NW_SRC_SHIFT = 8,
OFPFW_NW_SRC_BITS = 6,
OFPFW_NW_SRC_MASK = ((1 << OFPFW_NW_SRC_BITS) - 1) << OFPFW_NW_SRC_SHIFT,
OFPFW_NW_SRC_ALL = 32 << OFPFW_NW_SRC_SHIFT,
/* IP destination address wildcard bit count. Same format as source. */
OFPFW_NW_DST_SHIFT = 14,
OFPFW NW DST BITS = 6,
OFPFW NW DST MASK = ((1 << OFPFW NW DST BITS) - 1) << OFPFW NW DST SHIFT,
OFPFW_NW_DST_ALL = 32 << OFPFW_NW_DST_SHIFT,
/* Wildcard all fields. */
OFPFW_ALL = ((1 << 20) - 1)
};
```

The source and destination netmasks are each specified with a 6-bit number in the wildcard description. It is interpreted similar to the CIDR suffix, but with the opposite meaning, since this is being used to indicate which bits in the IP address should be treated as "wild". For example, a CIDR suffix of "24" means to use a netmask of "255.255.255.0". However, a wildcard mask value of "24" means that the least-significant 24-bits are wild, so it forms a netmask of "255.0.0.0".

### **B.6.2** New Physical Port Stats

The ofp\_port\_stats message has been expanded to return more information. If a switch does not support a particular field, it should set the value to have all bits enabled (i.e., a "-1" if the value were treated as signed). This is the new format:

```
/* Body of reply to OFPST_PORT request. If a counter is unsupported, set
 * the field to all ones. */
struct ofp_port_stats {
    uint16_t port_no;
```

```
uint8_t pad[6];
                             /* Align to 64-bits. */
    uint64_t rx_packets;
                             /* Number of received packets. */
    uint64_t tx_packets;
                             /* Number of transmitted packets. */
    uint64_t rx_bytes;
                             /* Number of received bytes. */
    uint64_t tx_bytes;
                             /* Number of transmitted bytes. */
    uint64_t rx_dropped;
                             /* Number of packets dropped by RX. */
    uint64_t tx_dropped;
                             /* Number of packets dropped by TX. */
    uint64_t rx_errors;
                             /* Number of receive errors. This is a super-set
                                of receive errors and should be great than or
                                equal to the sum of al rx_*_err values. */
                             /* Number of transmit errors. This is a super-set
    uint64_t tx_errors;
                                of transmit errors. */
                             /* Number of frame alignment errors. */
    uint64_t rx_frame_err;
    uint64_t rx_over_err;
                             /* Number of packets with RX overrun. */
    uint64_t rx_crc_err;
                             /* Number of CRC errors. */
    uint64_t collisions;
                             /* Number of collisions. */
};
```

#### B.6.3 IN\_PORT Virtual Port

The behavior of sending out the incoming port was not clearly defined in earlier versions of the specification. It is now forbidden unless the output port is explicitly set to OFPP\_IN\_PORT virtual port (0xfff8) is set. The primary place where this is used is for wireless links, where a packet is received over the wireless interface and needs to be sent to another host through the same interface. For example, if a packet needed to be sent to all interfaces on the switch, two actions would need to be specified: "actions=output:ALL,output:IN\_PORT".

# **B.6.4** Port and Link Status and Configuration

The switch should inform the controller of changes to port and link status. This is done with a new flag in ofp\_port\_config:

- OFPPC\_PORT\_DOWN The port has been configured "down".
- ... and a new flag in ofp\_port\_state:
  - OFPPS\_LINK\_DOWN There is no physical link present.

The switch should support enabling and disabling a physical port by modifying the OFPPFL\_PORT\_DOWN flag (and mask bit) in the ofp\_port\_mod message. Note that this is **not** the same as adding or removing the interface from the list of OpenFlow monitored ports; it is equivalent to "ifconfig ethO down" on Unix systems.

#### B.6.5 Echo Request/Reply Messages

The switch and controller can verify proper connectivity through the OpenFlow protocol with the new echo request (OFPT\_ECHO\_REQUEST) and reply (OFPT\_ECHO\_REPLY) messages. The body of the message is undefined and simply contains uninterpreted data that is to be echoed back to the requester. The requester matches the reply with the transaction id from the OpenFlow header.

### **B.6.6** Vendor Extensions

Vendors are now able to add their own extensions, while still being OpenFlow compliant. The primary way to do this is with the new OFPT\_VENDOR message type. The message body is of the form:

The *vendor* field is a 32-bit value that uniquely identifies the vendor. If the most significant byte is zero, the next three bytes are the vendor's IEEE OUI. If vendor does not have (or wish to use) their OUI, they should contact the OpenFlow consortium to obtain one. The rest of the body is uninterpreted.

It is also possible to add vendor extensions for stats messages with the OFPST\_VENDOR stats type. The first four bytes of the message are the vendor identifier as described earlier. The rest of the body is vendor-defined.

To indicate that a switch does not understand a vendor extension, a OFPBRC\_BAD\_VENDOR error code has been defined under the OFPET\_BAD\_REQUEST error type.

Vendor-defined actions are described below in the "Variable Length and Vendor Actions" section.

#### **B.6.7** Explicit Handling of IP Fragments

In previous versions of the specification, handling of IP fragments was not clearly defined. The switch is now able to tell the controller whether it is able to reassemble fragments. This is done with the following capabilities flag passed in the ofp\_switch features message:

```
OFPC_IP_REASM = 1 << 5 /* Can reassemble IP fragments. */
```

The controller can configure fragment handling in the switch through the setting of the following new ofp\_config\_flags in the ofp\_switch\_config message:

```
/* Handling of IP fragments. */
OFPC_FRAG_NORMAL = 0 << 1, /* No special handling for fragments. */
OFPC_FRAG_DROP = 1 << 1, /* Drop fragments. */
OFPC_FRAG_REASM = 2 << 1, /* Reassemble (only if OFPC_IP_REASM set). */
OFPC_FRAG_MASK = 3 << 1</pre>
```

"Normal" handling of fragments means that an attempt should be made to pass the fragments through the OpenFlow tables. If any field is not present (e.g., the TCP/UDP ports didn't fit), then the packet should not match any entry that has that field set.

### B.6.8 802.1D Spanning Tree

OpenFlow now has a way to configure and view results of on-switch implementations of 802.1D Spanning Tree Protocol.

A switch that implements STP must set the new OFPC\_STP bit in the 'capabilities' field of its OFPT\_FEATURES\_REPLY message. A switch that implements STP at all must make it available on all of its physical ports, but it need not implement it on virtual ports (e.g. OFPP\_LOCAL).

Several port configuration flags are associated with STP. The complete set of port configuration flags are:

```
enum ofp_port_config {
   OFPPC_PORT_DOWN = 1 << 0,    /* Port is administratively down. */
   OFPPC_NO_STP = 1 << 1,    /* Disable 802.1D spanning tree on port. */
   OFPPC_NO_RECV = 1 << 2,    /* Drop most packets received on port. */
   OFPPC_NO_RECV_STP = 1 << 3,    /* Drop received 802.1D STP packets. */
   OFPPC_NO_FLOOD = 1 << 4,    /* Do not include this port when flooding. */
   OFPPC_NO_FWD = 1 << 5,    /* Drop packets forwarded to port. */
   OFPPC_NO_PACKET_IN = 1 << 6    /* Do not send packet-in msgs for port. */
};</pre>
```

The controller may set OFPPFL\_NO\_STP to 0 to enable STP on a port or to 1 to disable STP on a port. (The latter corresponds to the Disabled STP port state.) The default is switch implementation-defined; the OpenFlow reference implementation by default sets this bit to 0 (enabling STP).

When OFPPFL\_NO\_STP is 0, STP controls the OFPPFL\_NO\_FLOOD and OFPPFL\_STP\_\* bits directly. OFPPFL\_NO\_FLOOD is set to 0 when the STP port state is Forwarding, otherwise to 1. The bits in OFPPFL\_STP\_MASK are set to one of the other OFPPFL\_STP\_\* values according to the current STP port state.

When the port flags are changed by STP, the switch sends an OFPT\_PORT\_STATUS message to notify the controller of the change. The OFPPFL\_NO\_RECV, OFPPFL\_NO\_RECV\_STP, OFPPFL\_NO\_FWD, and OFPPFL\_NO\_PACKET\_IN bits in the OpenFlow port flags may be useful for the controller to implement STP, although they interact poorly with in-band control.

# **B.6.9** Modify Actions in Existing Flow Entries

New ofp\_flow\_mod commands have been added to support modifying the actions of existing entries: OFPFC\_MODIFY and OFPFC\_MODIFY\_STRICT. They use the match field to describe the entries that should be modified with the supplied actions. OFPFC\_MODIFY is similar to OFPFC\_DELETE, in that wildcards are "active". OFPFC\_MODIFY\_STRICT is similar to OFPFC\_DELETE\_STRICT, in that wildcards are not "active", so both the wildcards and priority must match an entry. When a matching flow is found, only its actions are modified – information such as counters and timers are not reset.

If the controller uses the OFPFC\_ADD command to add an entry that already exists, then the new entry replaces the old and all counters and timers are reset.

### B.6.10 More Flexible Description of Tables

Previous versions of OpenFlow had very limited abilities to describe the tables supported by the switch. The n\_exact, n\_compression, and n\_general fields in ofp\_switch\_features have been replaced with n\_tables, which lists the number of tables in the switch.

The behavior of the OFPST\_TABLE stat reply has been modified slightly. The ofp\_table\_stats body now contains a wildcards field, which indicates the fields for which that particular table supports wildcarding. For example, a direct look-up hash table would have that field set to zero, while a sequentially searched table would have it set to OFPFW\_ALL. The ofp\_table\_stats entries are returned in the order that packets traverse the tables.

When the controller and switch first communicate, the controller will find out how many tables the switch supports from the Features Reply. If it wishes to understand the size, types, and order in which tables are consulted, the controller sends a OFPST\_TABLE stats request.

## **B.6.11 Lookup Count in Tables**

Table stats returned ofp\_table\_stats structures now return the number of packets that have been looked up in the table—whether they hit or not. This is stored in the lookup\_count field.

## B.6.12 Modifying Flags in Port-Mod More Explicit

The ofp\_port\_mod is used to modify characteristics of a switch's ports. A supplied ofp\_phy\_port structure describes the behavior of the switch through its flags field. However, it's possible that the controller wishes to change a particular flag and may not know the current status of all flags. A mask field has been added which has a bit set for each flag that should be changed on the switch.

The new ofp\_port\_mod message looks like the following:

# **B.6.13** New Packet-Out Message Format

The previous version's packet-out message treated the variable-length array differently depending on whether the buffer\_id was set or not. If set, the array consisted of actions to be executed and the out\_port was ignored. If not, the array consisted of the actual packet that should be placed on the wire through the out\_port interface. This was a bit ugly, and it meant that in order for a non-buffered packet to have multiple actions executed on it, that a new flow entry be created just to match that entry.

A new format is now used, which cleans the message up a bit. The packet always contains a list of actions. An additional variable-length array follows the list of actions with the contents of the packet if buffer\_id is not set. This is the new format:

## **B.6.14** Hard Timeout for Flow Entries

A hard timeout value has been added to flow entries. If set, then the entry must be expired in the specified number of seconds regardless of whether or not packets are hitting the entry. A hard\_timeout field has been added to the flow\_mod message to support this. The max\_idle field has been renamed idle\_timeout. A value of zero means that a timeout has not been set. If both idle\_timeout and hard\_timeout are zero, then the flow is permanent and should not be deleted without an explicit deletion.

The new ofp\_flow\_mod format looks like this:

```
struct ofp_flow_mod {
    struct ofp_header header;
    struct ofp_match match;
                                 /* Fields to match */
    /* Flow actions. */
    uint16_t command;
                                  /* One of OFPFC *. */
   uint16_t idle_timeout;
                                  /* Idle time before discarding (seconds). */
   uint16_t hard_timeout;
                                  /* Max time before discarding (seconds). */
    uint16_t priority;
                                  /* Priority level of flow entry. */
   uint32_t buffer_id;
                                  /* Buffered packet to apply to (or -1).
                                     Not meaningful for OFPFC_DELETE*. */
   uint32_t reserved;
                                  /* Reserved for future use. */
    struct ofp_action actions[0]; /* The number of actions is inferred from
                                     the length field in the header. */
};
```

Since flow entries can now be expired due to idle or hard timeouts, a reason field has been added to the ofp\_flow\_expired message. A value of 0 indicates an idle timeout and 1 indicates a hard timeout:

The new ofp\_flow\_expired message looks like the following:

```
struct ofp_flow_expired {
    struct ofp_header header;
    struct ofp_match match;
                             /* Description of fields */
    uint16_t priority;
                              /* Priority level of flow entry. */
    uint8_t reason;
                              /* One of OFPER_*. */
    uint8_t pad[1];
                              /* Align to 32-bits. */
    uint32_t duration;
                              /* Time flow was alive in seconds. */
    uint8_t pad2[4];
                              /* Align to 64-bits. */
    uint64_t packet_count;
    uint64_t byte_count;
};
```

# B.6.15 Reworked initial handshake to support backwards compatibility

OpenFlow now includes a basic "version negotiation" capability. When an OpenFlow connection is established, each side of the connection should immediately send an OFPT\_HELLO message as its first OpenFlow message. The 'version' field in the hello message should be the highest OpenFlow protocol version supported by the sender. Upon receipt of this message, the recipient may calculate the OpenFlow protocol version to be used as the smaller of the version number that it sent and the one that it received.

If the negotiated version is supported by the recipient, then the connection proceeds. Otherwise, the recipient must reply with a message of OFPT\_ERROR with a 'type' value of OFPET\_HELLO\_FAILED, a 'code' of OFPHFC\_COMPATIBLE, and optionally an ASCII string explaining the situation in 'data', and then terminate the connection.

The OFPT\_HELLO message has no body; that is, it consists only of an OpenFlow header. Implementations must be prepared to receive a hello message that includes a body, ignoring its contents, to allow for later extensions.

## **B.6.16** Description of Switch Stat

The OFPST\_DESC stat has been added to describe the hardware and software running on the switch:

It contains a 256 character ASCII description of the manufacturer, hardware type, and software version. It also contains a 32 character ASCII serial number. Each entry is padded on the right with 0 bytes.

# **B.6.17 Variable Length and Vendor Actions**

Vendor-defined actions have been added to OpenFlow. To enable more versatility, actions have switched from fixed-length to variable. All actions have the following header:

The length for actions must always be a multiple of eight to aid in 64-bit alignment. The action types are as follows:

```
enum ofp_action_type {
   OFPAT_OUTPUT,
                           /* Output to switch port. */
   OFPAT_SET_VLAN_VID,
                          /* Set the 802.1q VLAN id. */
    OFPAT_SET_VLAN_PCP, /* Set the 802.1q priority. */
    OFPAT_STRIP_VLAN,
                         /* Strip the 802.1q header. */
    OFPAT_SET_DL_SRC,
                         /* Ethernet source address. */
    OFPAT_SET_DL_DST,
                         /* Ethernet destination address. */
    OFPAT_SET_NW_SRC,
                         /* IP source address. */
    OFPAT_SET_NW_DST,
                         /* IP destination address. */
   OFPAT_SET_TP_SRC,
OFPAT_SET_TP_DST,
                         /* TCP/UDP source port. */
                           /* TCP/UDP destination port. */
    OFPAT_VENDOR = Oxffff
};
```

The vendor-defined action header looks like the following:

The vendor field uses the same vendor identifier described earlier in the "Vendor Extensions" section. Beyond using the ofp\_action\_vendor header and the 64-bit alignment requirement, vendors are free to use whatever body for the message they like.

### **B.6.18 VLAN Action Changes**

It is now possible to set the priority field in VLAN tags and stripping VLAN tags is now a separate action. The OFPAT\_SET\_VLAN\_VID action behaves like the former OFPAT\_SET\_DL\_VLAN action, but no longer accepts a special value that causes it to strip the VLAN tag. The OFPAT\_SET\_VLAN\_PCP action modifies the 3-bit priority field in the VLAN tag. For existing tags, both actions only modify the bits associated with the field being updated. If a new VLAN tag needs to be added, the value of all other fields is zero.

The OFPAT\_SET\_VLAN\_VID action looks like the following:

```
struct ofp_action_vlan_vid {
    uint16_t type;
                                    /* OFPAT_SET_VLAN_VID. */
    uint16_t len;
                                    /* Length is 8. */
                                    /* VLAN id. */
    uint16_t vlan_vid;
    uint8_t pad[2];
};
The OFPAT_SET_VLAN_PCP action looks like the following:
struct ofp_action_vlan_pcp {
    uint16_t type;
                                    /* OFPAT_SET_VLAN_PCP. */
    uint16_t len;
                                    /* Length is 8. */
    uint8_t vlan_pcp;
                                    /* VLAN priority. */
    uint8_t pad[3];
};
```

The OFPAT STRIP VLAN action takes no argument and strips the VLAN tag if one is present.

# B.6.19 Max Supported Ports Set to 65280

What: Increase maximum number of ports to support large vendor switches; was previously 256, chosen arbitrarily.

Why: The HP 5412 chassis supports 288 ports of Ethernet, and some Cisco switches go much higher. The current limit (OFPP\_MAX) is 255, set to equal the maximum number of ports in a bridge segment in the 1998 STP spec. The RSTP spec from 2004 supports up to 4096 (12 bits) of ports.

**How:** Change OFPP\_MAX to 65280. (However, out of the box, the reference switch implementation supports at most 256 ports.)

# B.6.20 Send Error Message When Flow Not Added Due To Full Tables

The switch now sends an error message when a flow is added, but cannot because all the tables are full. The message has an error type of OFPET\_FLOW\_MOD\_FAILED and code of OFPFMFC\_ALL\_TABLES\_FULL. If the Flow-Mod command references a buffered packet, then actions are not performed on the packet. If the controller wishes the packet to be sent regardless of whether or not a flow entry is added, then it should use a Packet-Out directly.

### **B.6.21** Behavior Defined When Controller Connection Lost

What: Ensure that all switches have at least one common behavior when the controller connection is lost.

Why: When the connection to the controller is lost, the switch should behave in a well-defined way. Reasonable behaviors include 'do nothing - let flows naturally timeout', 'freeze timeouts', 'become learning switch', and 'attempt connection to other controller'. Switches may implement one or more of these, and network admins may want to ensure that if the controller goes out, they know what the network can do.

The first is the simplest: ensure that every switch implements a default of 'do nothing - let flows timeout naturally'. Changes must be done via vendor-specific command line interface or vendor extension OpenFlow messages.

The second may help ensure that a single controller can work with switches from multiple vendors. The different failure behaviors, plus 'other', could be feature bits set for the switch. A switch would still only have to support the default.

The worry here is that we may not be able to enumerate in advance the full range of failure behaviors, which argues for the first approach.

**How:** Added text to spec: "In the case that the switch loses contact with the controller, the default behavior must be to do nothing - to let flows timeout naturally. Other behaviors can be implemented via vendor-specific command line interface or vendor extension OpenFlow messages."

# B.6.22 ICMP Type and Code Fields Now Matchable

What: Allow matching ICMP traffic based on type or code.

Why: We can't distinguish between different types of ICMP traffic (e.g., echo replies vs echo requests vs redirects).

**How:** Changed spec to allow matching on these fields.

As for implementation: The type and code are each a single byte, so they easily fit in our existing flow structure. Overload the tp\_src field to ICMP type and tp\_dst to ICMP code. Since they are only a single byte, they will reside in the low-byte of these two byte fields (stored in network-byte order). This will allow a controller to use the existing wildcard bits to wildcard these ICMP fields.

## B.6.23 Output Port Filtering for Delete\*, Flow Stats and Aggregate Stats

Add support for listing and deleting entries based on an output port.

To support this, an out\_port field has been added to the ofp\_flow\_mod, ofp\_flow\_stats\_request, and ofp\_aggregate\_stats\_request messages. If an out\_port contains a value other than OFPP\_NONE, it introduces a constraint when matching. This constraint is that the rule must contain an output action directed at that port. Other constraints such as ofp\_match structs and priorities are still used; this is purely an \*additional\* constraint. Note that to get previous behavior, though, out\_port must be set

to OFPP\_NONE, since "0" is a valid port id. This only applies to the delete and delete\_strict flow mod commands; the field is ignored by add, modify, and modify\_strict.

# B.7 OpenFlow version 0.9

Release date: July 20, 2009 Protocol version: 0x98

#### B.7.1 Failover

The reference implementation now includes a simple failover mechanism. A switch can be configured with a list of controllers. If the first controller fails, it will automatically switch over to the second controller on the list.

# **B.7.2** Emergency Flow Cache

The protocol and reference implementation have been extended to allow insertion and management of emergency flow entries.

Emergency-specific flow entries are inactive until a switch loses connectivity from the controller. If this happens, the switch invalidates all normal flow table entries and copies all emergency flows into the normal flow table.

Upon connecting to a controller again, all entries in the flow cache stay active. The controller then has the option of resetting the flow cache if needed.

#### B.7.3 Barrier Command

The Barrier Command is a mechanism to get notified when an OpenFlow message has finished executing on the switch. When a switch receives a Barrier message it must first complete all commands sent before the Barrier message before executing any commands after it. When all commands before the Barrier message have completed, it must send a Barrier Reply message back to the controller.

### **B.7.4** Match on VLAN Priority Bits

There is an optional new feature that allows matching on priority VLAN fields. Pre 0.9, the VLAN id is a field used in identifying a flow, but the priority bits in the VLAN tag are not. In this release we include the priority bits as a separate field to identify flows. Matching is possible as either an exact match on the 3 priority bits, or as a wildcard for the entire 3 bits.

#### **B.7.5** Selective Flow Expirations

Flow expiration messages can now be requested on a per-flow, rather than per-switch granularity.

### B.7.6 Flow Mod Behavior

There now is a CHECK\_OVERLAP flag to flow mods which requires the switch to do the (potentially more costly) check that there doesn't already exist a conflicting flow with the same priority. If there is one, the mod fails and an error code is returned. Support for this flag is required in an OpenFlow switch.

### **B.7.7 Flow Expiration Duration**

The meaning of the "duration" field in the Flow Expiration message has been changed slightly. Previously there were conflicting definitions of this in the spec. In 0.9 the value returned will be the time that the flow was active and not include the timeout period.

#### **B.7.8** Notification for Flow Deletes

If a controller deletes a flow it now receives a notification if the notification bit is set. In previous releases only flow expirations but not delete actions would trigger notifications.

# B.7.9 Rewrite DSCP in IP ToS header

There is now an added Flow action to rewrite the DiffServ CodePoint bits part of the IP ToS field in the IP header. This enables basic support for basic QoS with OpenFlow in some switches. A more complete QoS framework is planned for a future OpenFlow release.

#### B.7.10 Port Enumeration now starts at 1

Previous releases of OpenFlow had port numbers start at 0, release 0.9 changes them to start at 1.

#### **B.7.11** Other changes to the Specification

- 6633/TCP is now the recommended default OpenFlow Port. Long term the goal is to get a IANA approved port for OpenFlow.
- The use of "Type 1" and "Type 0" has been deprecated and references to it have been removed.
- Clarified Matching Behavior for Flow Modification and Stats
- Made explicit that packets received on ports that are disabled by spanning tree must follow the normal flow table processing path.
- Clarified that transaction ID in header should match offending message for OFPET\_BAD\_REQUEST,
   OFPET\_BAD\_ACTION, OFPET\_FLOW\_MOD\_FAILED.
- Clarified the format for the Strip VLAN Action
- Clarify behavior for packets that are buffered on the switch while switch is waiting for a reply from controller
- Added the new EPERM Error Type
- Fixed Flow Table Matching Diagram
- Clarified datapath ID 64 bits, up from 48 bits
- Clarified miss-send-len and max-len of output action

# B.8 OpenFlow version 1.0

Release date: December 31, 2009

Protocol version: 0x01

# B.8.1 Slicing

OpenFlow now supports multiple queues per output port. Queues support the ability to provide minimum bandwidth guarantees; the bandwidth allocated to each queue is configurable. The name slicing is derived from the ability to provide a slice of the available network bandwidth to each queue.

#### B.8.2 Flow cookies

Flows have been extended to include an opaque identifier, referred to as a cookie. The cookie is specified by the controller when the flow is installed; the cookie will be returned as part of each flow stats and flow expired message.

## B.8.3 User-specifiable datapath description

The OFPST\_DESC (switch description) reply now includes a datapath description field. This is a user-specifiable field that allows a switch to return a string specified by the switch owner to describe the switch.

# B.8.4 Match on IP fields in ARP packets

The reference implementation can now match on IP fields inside ARP packets. The source and destination protocol address are mapped to the nw\_src and nw\_dst fields respecitively, and the opcode is mapped to the nw\_proto field.

# B.8.5 Match on IP ToS/DSCP bits

OpenFlow now supports matching on the IP ToS/DSCP bits.

# B.8.6 Querying port stats for individual ports

Port stat request messages include a port\_no field to allow stats for individual ports to be queried. Port stats for all ports can still be requested by specifying OFPP\_NONE as the port number.

### B.8.7 Improved flow duration resolution in stats/expiry messages

Flow durations in stats and expiry messages are now expressed with nanosecond resolution. Note that the accuracy of flow durations in the reference implementation is on the order of milliseconds. (The actual accuracy is in part dependent upon kernel parameters.)

### **B.8.8** Other changes to the Specification

- remove multi\_phy\_tx spec text and capability bit
- clarify execution order of actions
- replace SSL refs with TLS
- resolve overlap ambiguity
- clarify flow mod to non-existing port
- clarify port definition
- update packet flow diagram
- update header parsing diagram for ICMP
- fix English ambiguity for flow-removed messages
- fix async message English ambiguity
- note that multiple controller support is undefined
- clarify that byte equals octet
- note counter wrap-around
- removed warning not to build a switch from this specification

# B.9 OpenFlow version 1.1

Release date: February 28, 2011

Protocol version: 0x02

#### **B.9.1** Multiple Tables

Prior versions of the OpenFlow specification did expose to the controller the abstraction of a single table. The OpenFlow pipeline could internally be mapped to multiple tables, such as having a separate wildcard and exact match table, but those tables would always act logically as a single table.

OpenFlow 1.1 introduces a more flexible pipeline with multiple tables. Exposing multiple tables has many advantages. The first advantage is that a lot of hardware has multiple tables internally (for example L2 table, L3 table, multiple TCAM lookups), and the multiple tables support of OpenFlow may enable to expose this hardware with greater efficiency and flexibility. The second advantage is that many network deployments combine orthogonal processing of packets (for example ACL, QoS and routing), forcing all those processing in a single table creates huge ruleset due to the cross product of individual rules. Multiple tables may decouple properly that processing properly.

The new OpenFlow pipeline with multiple tables is quite different from the simple pipeline of prior OpenFlow versions. The new OpenFlow pipeline exposes a set of completely generic tables, supporting the full match and full set of actions. It's difficult to build a pipeline abstraction that represents accurately all possible hardware, therefore OpenFlow 1.1 is based on a generic and flexible pipeline that

may be mapped to the hardware. Some limited table capabilities are available to denote what each table is capable of supporting.

Packets are processed through the pipeline, they are matched and processed in the first table, and may be matched and processed in other tables. As it goes through the pipeline, a packet is associated with an *action set*, accumulating action, and a generic *metadata* register. The action set is resolved at the end of the pipeline and applied to the packet. The metadata can be matched and written at each table and allows state to be carried between tables.

OpenFlow introduces a new protocol object called *instruction* to control pipeline processing. Actions which were directly attached to flows in previous versions are now encapsulated in instructions, instructions may apply those actions between tables or accumulate them in the packet action set. Instructions can also change the *metadata*, or direct a packet to another table.

- The switch now exposes a pipeline with multiple tables
- Flow entries have instructions to control pipeline processing
- Controllers can choose packet traversal of tables via goto instruction
- Metadata field (64 bits) can be set and matched in tables
- Packet actions can be merged in packet action set
- Packet action set is executed at the end of pipeline
- Packet actions can be applied between table stages
- Table miss can send to controller, continue to next table or drop
- Rudimentary table capability and configuration

# **B.9.2** Groups

The new group abstraction enables OpenFlow to represent a set of ports as a single entity for forwarding packets. Different types of groups are provided, to represent different abstractions such as multicasting or multipathing. Each group is composed of a set group buckets, each group bucket contains the set of actions to be applied before forwarding to the port. Groups buckets can also forward to other groups, enabling groups to be chained together.

- Group indirection to represent a set of ports
- Group table with 4 types of groups:
  - All used for multicast and flooding
  - Select used for multipath
  - Indirect simple indirection
  - Fast Failover use first live port
- Group action to direct a flow to a group
- Group buckets contains actions related to the individual port

### B.9.3 Tags: MPLS & VLAN

Prior versions of the OpenFlow specification had limited VLAN support, it only supported a single level of VLAN tagging with ambiguous semantic. The new tagging support has explicit actions to add, modify and remove VLAN tags, and can support multiple levels of VLAN tagging. It also adds similar support the MPLS shim headers.

- Support for VLAN and QinQ, adding, modifying and removing VLAN headers
- Support for MPLS, adding, modifying and removing MPLS shim headers

# **B.9.4** Virtual ports

Prior versions of the OpenFlow specification assumed that all the ports of the OpenFlow switch were physical ports. This version of the specification adds support for virtual ports, which can represent complex forwarding abstractions such as LAGs or tunnels.

- Make port number 32 bits, enable larger number of ports
- Enable switch to provide virtual ports as OpenFlow ports
- Augment packet-in to report both virtual and physical ports

#### B.9.5 Controller connection failure

Prior versions of the OpenFlow specification introduced the emergency flow cache as a way to deal with the loss of connectivity with the controller. The emergency flow cache feature was removed in this version of the specification, due to the lack of adoption, the complexity to implement it and other issues with the feature semantic.

This version of the specification adds two simpler modes to deal with the loss of connectivity with the controller. In fail secure mode, the switch continues operating in OpenFlow mode, until it reconnects to a controller. In fail standalone mode, the switch reverts to using normal processing (Ethernet switching).

- Remove Emergency Flow Cache from spec
- Connection interruption triggers fail secure or fail standalone mode

### B.9.6 Other changes

- Remove 802.1d-specific text from the specification
- Cookie Enhancements Proposal cookie mask for filtering
- Set\_queue action (unbundled from output port action)
- Maskable DL and NW address match fields
- Add TTL decrement, set and copy actions for IPv4 and MPLS
- SCTP header matching and rewriting support
- Set ECN action
- Define message handling: no loss, may reorder if no barrier
- Rename VENDOR APIs to EXPERIMENTER APIs
- Many other bug fixes, rewording and clarifications

# B.10 OpenFlow version 1.2

Release date: December 5, 2011

Protocol version: 0x03

Please refer to the bug tracking ID for more details on each change.

#### B.10.1 Extensible match support

Prior versions of the OpenFlow specification used a static fixed length structure to specify ofp\_match, which prevents flexible expression of matches and prevents inclusion of new match fields. The ofp\_match has been changed to a TLV structure, called OpenFlow Extensible Match (OXM), which dramatically increases flexibility.

The match fields themselves have been reorganised. In the previous static structure, many fields were overloaded; for example tcp.src\_port, udp.src\_port, and icmp.code were using the same field entry. Now, every logical field has its own unique type.

List of features for OpenFlow Extensible Match :

- Flexible and compact TLV structure called OXM (EXT-1)
- Enable flexible expression of match, and flexible bitmasking (EXT-1)
- Pre-requisite system to insure consistency of match (EXT-1)
- Give every match field a unique type, remove overloading (EXT-1)
- Modify VLAN matching to be more flexible (EXT-26)
- Add vendor classes and experimenter matches (EXT-42)
- Allow switches to override match requirements (EXT-56, EXT-33)

### B.10.2 Extensible 'set\_field' packet rewriting support

Prior versions of the OpenFlow specification used hand-crafted actions to rewrite header fields. The Extensible set\_field action reuses the OXM encoding defined for matches, and permits the rewriting of any header field in a single action (EXT-13). This allows any new match field, including experimenter fields, to be available for rewrite. This makes the specification cleaner and eases cost of introducing new fields.

- Deprecate most header rewrite actions
- Introduce generic set-field action (EXT-13)
- Reuse match TLV structure (OXM) in set-field action

#### B.10.3 Extensible context expression in 'packet-in'

The packet-in message did include some of the packet context (ingress port), but not all (metadata), preventing the controller from determining how a match happened in the table and which flow entries would match or not match. Rather than introduce a hard coded field in the packet-in message, the flexible OXM encoding is used to carry packet context.

- Reuse match TLV structure (OXM) to describe metadata in packet-in (EXT-6)
- Include the 'metadata' field in packet-in
- Move ingress port and physical port from static field to OXM encoding
- Allow to optionally include packet header fields in TLV structure

#### B.10.4 Extensible Error messages via experimenter error type

An experimenter error code has been added, enabling experimenter functionality to generate custom error messages (EXT-2). The format is identical to other experimenter APIs.

#### B.10.5 IPv6 support added

Basic support for IPv6 match and header rewrite has been added, via the Flexible match support.

- Added support for matching on IPv6 source address, destination address, protocol number, traffic class, ICMPv6 type, ICMPv6 code and IPv6 neighbor discovery header fields (EXT-1)
- Added support for matching on IPv6 flow label (EXT-36)

### B.10.6 Simplified behaviour of flow-mod request

The behaviour of flow-mod request has been simplified (EXT-30).

- MODIFY and MODIFY\_STRICT commands never insert new flows in the table
- New flag OFPFF\_RESET\_COUNTS to control counter reset
- Remove quirky behaviour for cookie field.

### B.10.7 Removed packet parsing specification

The OpenFlow specification no longer attempts to define how to parse packets (EXT-3). The match fields are only defined logically.

- OpenFlow does not mandate how to parse packets
- Parsing consistency acheived via OXM pre-requisite

### B.10.8 Controller role change mechanism

The controller role change mechanism is a simple mechanism to support multiple controllers for failover (EXT-39). This scheme is entirely driven by the controllers; the switch only needs to remember the role of each controller to help the controller election mechanism.

- Simple mechanism to support multiple controllers for failover
- Switches may now connect to multiple controllers in parallel
- Enable each controller to change its roles to equal, master or slave

#### B.10.9 Other changes

- Per-table metadata bitmask capabilities (EXT-34)
- Rudimentary group capabilities (EXT-61)
- Add hard timeout info in flow-removed messages (OFP-283)
- Add ability for controller to detect STP support(OFP-285)
- Turn off packet buffering with OFPCML\_NO\_BUFFER (EXT-45)
- Added ability to query all queues (EXT-15)
- Added experimenter queue property (EXT-16)
- Added max-rate queue property (EXT-21)
- Enable deleting flow in all tables (EXT-10)
- Enable switch to check chaining when deleting groups (EXT-12)
- Enable controller to disable buffering (EXT-45)
- Virtual ports renamed logical ports (EXT-78)
- New error messages (EXT-1, EXT-2, EXT-12, EXT-13, EXT-39, EXT-74 and EXT-82)
- Include release notes into the specification document
- Many other bug fixes, rewording and clarifications

# B.11 OpenFlow version 1.3

Release date: April 13, 2012 Protocol version: 0x04

Please refers to the bug tracking ID for more details on each change.

#### B.11.1 Refactor capabilities negotiation

Prior versions of the OpenFlow specification included limited expression of the capabilities of an OpenFlow switch. OpenFlow 1.3 includes a more flexible framework to express capabilities (EXT-123).

The main change is the improved description of table capabilities. Those capabilities have been moved out of the table statistics structure in its own request/reply message, and encoded using a flexible TLV format. This enables the additions of next-table capabilities, table-miss flow entry capabilities and experimenter capabilities.

Other changes include renaming the 'stats' framework into the 'multipart' framework to reflect the fact that it is now used for both statistics and capabilities, and the move of port descriptions into its own multipart message to enable support of a greater number of ports.

List of features for Refactor capabilities negotiation:

- Rename 'stats' framework into the 'multipart' framework.
- Enable 'multipart' requests (requests spanning multiple messages).
- Move port list description to its own multipart request/reply.
- Move table capabilities to its own multipart request/reply.
- Create flexible property structure to express table capabilities.
- Enable to express experimenter capabilities.
- Add capabilities for table-miss flow entries.

• Add next-table (i.e. goto) capabilities

### B.11.2 More flexible table miss support

Prior versions of the OpenFlow specification included table configuration flags to select one of three 3 behaviour for handling table-misses (packet not matching any flows in the table). OpenFlow 1.3 replace those limited flags with the table-miss flow entry, a special flow entry describing the behaviour on table miss (EXT-108).

The table-miss flow entry uses standard OpenFlow instructions and actions to process table-miss packets, this enables to use OpenFlow's full flexibility in processing those packets. All previous behaviour expressed by the table-miss config flags can be expressed using the table-miss flow entry. Many new ways of handling a table-miss, such as processing table-miss with normal, can now trivially be described by the OpenFlow protocol.

- Remove table-miss config flags (EXT-108).
- Define table-miss flow entry as the all wildcard, lowest priority flow entry (EXT-108).
- Mandate support of the table-miss flow entry in every table to process table-miss packets (EXT-108).
- Add capabilities to describe the table-miss flow entry (EXT-123).
- Change table-miss default to drop packets (EXT-119).

### B.11.3 IPv6 Extension Header handling support

Add the ability to match the presence of common IPv6 extension headers, and some anomalous conditions in IPv6 extension headers (EXT-38). A new OXM pseudo header field OXM\_OF\_IPV6\_EXTHDR enables to match the following conditions:

- Hop-by-hop IPv6 extension header is present.
- Router IPv6 extension header is present.
- Fragmentation IPv6 extension header is present.
- Destination options IPv6 extension headers is present.
- Authentication IPv6 extension header is present.
- Encrypted Security Payload IPv6 extension header is present.
- No Next Header IPv6 extension header is present.
- IPv6 extension headers out of preferred order.
- Unexpected IPv6 extension header encountered.

#### **B.11.4** Per flow meters

Add support for per-flow meters (EXT-14). Per-flow meters can be attached to flow entries and can measure and control the rate of packets. One of the main applications of per-flow meters is to rate limit packets sent to the controller.

The per-flow meter feature is based on a new flexible meter framework, which includes the ability to describe complex meters through the use of multiple metering bands, metering statistics and capabilities. Currently, only simple rate-limiter meters are defined over this framework. Support for color-aware

meters, which support Diff-Serv style operation and are tightly integrated in the pipeline, was postponed to a later release.

- Flexible meter framework based on per-flow meters and meter bands.
- Meter statistics, including per band statistics.
- Enable to attach meters flexibly to flow entries.
- Simple rate-limiter support (drop packets).

# B.11.5 Per connection event filtering

Version 1.2 of the specification introduced the ability for a switch to connect to multiple controllers for fault tolerance and load balancing. Per connection event filtering improves the multi-controller support by enabling each controller to filter events from the switch it does not want (EXT-120).

A new set of OpenFlow messages enables a controller to configure an event filter on its own connection to the switch. Asynchronous messages can be filtered by type and reason. This event filter comes in addition to other existing mechanisms that enable or disable asynchronous messages, for example the generation of flow-removed events can be configured per flow. Each controller can have a separate filter for the slave role and the master/equal role.

- Add asynchronous message filter for each controller connection.
- Controller message to set/get the asynchronous message filter.
- Set default filter value to match OpenFlow 1.2 behaviour.
- Remove OFPC\_INVALID\_TTL\_TO\_CONTROLLER config flag.

# **B.11.6** Auxiliary connections

In previous versions of the specification, the channel between the switch and the controller is exclusively made of a single TCP connection, which does not allow to exploit the parallelism available in most switch implementations. OpenFlow 1.3 enables a switch to create auxiliary connections to supplement the main connection between the switch and the controller (EXT-114). Auxiliary connections are mostly useful to carry packet-in and packet-out messages.

- Enable switch to create auxiliary connections to the controller.
- Mandate that auxiliary connection can not exist when main connection is not alive.
- Add auxiliary-id to the protocol to disambiguate the type of connection.
- Enable auxiliary connection over UDP and DTLS.

# B.11.7 MPLS BoS matching

A new OXM field OXM\_OF\_MPLS\_BOS has been added to match the Bottom of Stack bit (BoS) from the MPLS header (EXT-85). The BoS bit indicates if other MPLS shim headers are in the payload of the present MPLS packet, and matching this bit can help to disambiguate cases where the MPLS label is reused across levels of MPLS encapsulation.

#### B.11.8 Provider Backbone Bridging tagging

Add support for tagging packets using Provider Backbone Bridging (PBB) encapsulation (EXT-105). This enables OpenFlow to support various network deployments based on PBB, such as regular PBB and PBB-TE.

- Push and Pop operation to add PBB header as a tag.
- New OXM field to match I-SID for the PBB header.

#### B.11.9 Rework tag order

In previous versions of the specification, the final order of tags in a packet was statically specified. For example, an MPLS shim header was always inserted after all VLAN tags in the packet. OpenFlow 1.3 removes this restriction, the final order of tags in a packet is dictated by the order of the tagging operations, each tagging operation adds its tag in the outermost position (EXT-121).

- Remove defined order of tags in packet from the specification.
- Tags are now always added in the outermost possible position.
- Action-list can add tags in arbitrary order.
- Tag order is predefined for tagging in the action-set.

#### B.11.10 Tunnel-ID metadata

The logical port abstraction enables OpenFlow to support a wide variety of encapsulations. The tunnel-id metadata OXM\_OF\_TUNNEL\_ID is a new OXM field that exposes metadata associated with the logical port to the OpenFlow pipeline. It is most commonly the demultiplexing field from the encapsulation header (EXT-107).

For example, if the logical port performs GRE encapsulation, the tunnel-id field would map to the GRE key field from the GRE header. After decapsulation, OpenFlow would be able to match the GRE key in the tunnel-id match field. Similarly, by setting the tunnel-id, OpenFlow would be able to set the GRE key in an encapsulated packet.

#### B.11.11 Cookies in packet-in

A cookie field was added to the packet-in message (EXT-7). This field takes its value from the flow that sends the packet to the controller. If the packet was not sent by a flow, this field is set to 0xfffffffffffff.

Having the cookie in the packet-in enables the controller to more efficiently classify packet-in, rather than having to match the packet against the full flow table.

# **B.11.12** Duration for stats

A duration field was added to most statistics, including port statistics, group statistics, queue statistics and meter statistics (EXT-102). The duration field enables to more accurately calculate packet and byte rate from the counters included in those statistics.

#### B.11.13 On demand flow counters

New flow-mod flags have been added to disable packet and byte counters on a per-flow basis. Disabling such counters may improve flow handling performance in the switch.

### **B.11.14** Other changes

- Fix a bug describing VLAN matching (EXT-145).
- Flow entry description now mention priority (EXT-115).
- Flow entry description now mention timeout and cookies (EXT-147).
- Unavailable counters must now be set to all 1 (EXT-130).
- Correctly refer to flow entry instead of rule (EXT-132).
- Many other bug fixes, rewording and clarifications.

# B.12 OpenFlow version 1.3.1

Release date: September 06, 2012

Protocol version: 0x04

Please refers to the bug tracking ID for more details on each change.

### **B.12.1** Improved version negotiation

Prior versions of the OpenFlow specification included a simple scheme for version negotiation, picking the lowest of the highest version supported by each side. Unfortunately this scheme does not work properly in all cases, if both implementations don't implement all versions up to their highest version, the scheme can fail to negotiate a version they have in common (EXT-157).

The main change is adding a bitmap of version numbers in the Hello messages using during negotiation. By having the full list of version numbers, negotiation can always negotiate the appropriate version if one is available. This version bitmap is encoded in a flexible TLV format to retain future extensibility of the Hello message.

List of features for Improved version negotiation:

- Hello Elements, new flexible TLV format for Hello message
- Optional version bitmap in Hello messages.
- Improve version negotiation using optional version bitmaps.

# B.12.2 Other changes

- Mandate that table-miss flow entry support drop and controller (EXT-158).
- Clarify the mapping of encapsulation data in OXM\_OF\_TUNNEL\_ID (EXT-161).
- Rules and restrictions for UDP connections (EXT-162).
- Clarify virtual meters (EXT-165).
- Remove reference to switch fragmentation confusing (EXT-172).
- Fix meter constant names to always be multipart (OFPST\_ => OFPMT\_) (EXT-184).

- Add OFPG \* definitions to spec (EXT-198).
- Add ofp\_instruction and ofp\_table\_feature\_prop\_header in spec text (EXT-200).
- Bad error code in connection setup, must be OFPHFC\_INCOMPATIBLE (EXT-201).
- Instructions must be a multiple of 8 bytes in length (EXT-203).
- Port status includes a reason, not a status (EXT-204).
- Clarify usage of table config field (EXT-205).
- Clarify that required match fields don't need to be supported in every flow table (EXT-206).
- Clarify that prerequisite does not require full match field support (EXT-206).
- Include in the spec missing definitions from openflow.h (EXT-207).
- Fix invalid error code OFPQCFC\_EPERM -> OFPSCFC\_EPERM (EXT-208).
- Clarify PBB language about B-VLAN (EXT-215)
- Fix inversion between source and destination ethernet addresses (EXT-215)
- Clarify how to reorder group buckets, and associated group bucket clarifications (EXT-217).
- Add disclaimer that release notes may not match specification (EXT-218)
- Figure 1 still says "Secure Channel" (EXT-222).
- OpenFlow version must be calculated (EXT-223).
- Meter band drop precedence should be increased, not reduced (EXT-225)
- Fix ambiguous uses of may/can/should/must (EXT-227)
- Fix typos (EXT-228)
- Many typos (EXT-231)

# B.13 OpenFlow version 1.3.2

Release date : April 25, 2013 Protocol version : 0x04

Please refers to the bug tracking ID for more details on each change.

### B.13.1 Changes

- Mandate in OXM that 0-bits in mask must be 0-bits in value (EXT-238).
- Allow connection initiated from one of the controllers (EXT-252).
- Add clause on frame misordering to spec (EXT-259).
- Set table features doesn't generate flow removed messages (EXT-266).
- Fix description of set table features error response (EXT-267).
- Define use of generation\_id in role reply messages (EXT-272).
- Switches with only one flow table are not mandated to implement goto (EXT-280).

# **B.13.2** Clarifications

- Clarify that MPLS Pop action uses Ethertype regardless of BOS bit (EXT-194).
- Controller message priorities using auxiliary connections (EXT-240).
- Clarify padding rules and variable size arrays (EXT-251).
- Better description buffer-id in flow mod (EXT-257).
- Semantic of OFPPS\_LIVE (EXT-258).
- Improve multipart introduction (EXT-263).

- Clarify set table features description (EXT-266).
- Clarify meter flags and burst fields (EXT-270).
- Clarify slave access rights (EXT-271).
- Clarify that a switch can't change a controller role (EXT-276).
- Clarify roles of coexisting master and equal controllers (EXT-277).
- Various typos and rewording (EXT-282, EXT-288, EXT-290)

# B.14 OpenFlow version 1.3.3

Release date: September 27, 2013

Protocol version: 0x04

Please refers to the bug tracking ID for more details on each change.

### B.14.1 Changes

- Update with IANA registered TCP port: 6653 (EXT-133).
- Clarify that IPv6 flow label is not maskable by default (EXT-101).
- Clarify multipart segmentation rules, clarify use of empty multipart messages (EXT-321).
- Specify the normal fragment handling is mandatory, drop/reasm optional (EXT-99).
- Explain that prerequisites are cumulative (EXT-285).
- Specify that buffer-id is unique per connection (EXT-286).
- Clarify which OXM types can be used in set-field actions (EXT-289).
- Define oxm\_len for OXM IDs in table feature to have the payload length (EXT-330).
- Set-field prerequisite may be met through other actions (EXT-331).
- Clarify error codes for invalid group type and invalid weight (EXT-344).
- Specify group and meter feature bitmaps (EXT-345).

# **B.14.2** Clarifications

- Explain that OFP\_TABLE\_MOD is deprecated in 1.3.X (EXT-269).
- Minor clarification, replace "Goto" with "Goto-Table", replace "read message" with "multipart message" (EXT-297).
- Mention flags in the description of flow entries (EXT-298).
- Clarify policing of packet-in to controllers (EXT-300).
- Clarify invalid DSCP values, all six bits are valid (EXT-305).
- Add many new definitions to the glossary (EXT-309).
- Improve many existing glossary definitions (EXT-309).
- Detail UDP congestion control for auxiliary channels (EXT-311).
- Better document controller initiated connections (EXT-311).
- Clarify that there is only one request/reply per multipart sequence (EXT-321).
- Clarify connection maintenance messages on auxiliary connections (EXT-323).
- Clarify padding in set-field and hello elements (EXT-326).
- Clarify padding, data and total\_len fields in packet-in (EXT-286).
- Clarify that actions in table-feature don't have padding (EXT-287).
- In fail-standalone, the switch owns the flow tables and flow entries (EXT-291).

- Clarify queue relation to ports and packets, and that queues are optional (EXT-293).
- Action set may be executed before generating packet-in (EXT-296).
- Add bytes column in table describing OXM types (EXT-313).
- Clarify that OFPP\_MAX is a usable port number (EXT-315).
- Specify how to pack OpenFlow messages in UDP (EXT-332).
- Flow-mod modify: instructions are replaced, not updated (EXT-294).
- Clarify that OFPBAC\_BAD\_TYPE applies to unsupported actions (EXT-343).
- Explain flow removed reasons in the spec (EXT-261).
- Removing ports does not remove flow entries (EXT-281).
- Clarify that header field must be presents for set-field action (EXT-331).
- Clarify default values for fields on push-tag action (EXT-342).
- Clarify the use of the priority field in flow-mods (EXT-354).
- Replace WhitePaper specific URL with ONF generic URL (EXT-83/EXT-356).
- Clarify that the action-set is not always executed (EXT-359).
- Connection setup may be for an in-band connection (EXT-359).
- Clarify error for group forwarding to invalid group (EXT-359).
- Replace "OpenFlow protocol" into "OpenFlow switch protocol" (EXT-357).
- Replace "wire protocol" with "protocol version"

# B.15 OpenFlow version 1.3.4

Release date: March 27, 2014

Protocol version: 0x04

Please refers to the bug tracking ID for more details on each change.

### B.15.1 Changes

- Make IPv6 flow label maskable (EXT-101).
- Clarify statistics when group/meter are modified (EXT-341).
- Clarify that table feature match list should not include prerequisite only fields (EXT-387).
- Clarify table feature wildcard list should not include fields that are mandatory in some context only (EXT-387).
- Add section about control channel maintenance (EXT-435).
- Push MPLS should add a MPLS header before the IP header and before MPLS tags, not before VLAN which is not valid (EXT-457).

# **B.15.2** Clarifications

- Specify error for bad meter in meter action (EXT-237).
- Fix invalid prefix on meter multipart constants (EXT-302).
- Add a section about reserved values and reserved bit positions (EXT-360).
- Better describe the protocol basic format (EXT-360).
- Fix comment about experimenter band type (EXT-363).
- Clarify that port description multipart only list standard ports (EXT-364).
- Update flow-mod description with OFPFF\_RESET\_COUNTS (EXT-365).

- Clarify flow count for meter stats (EXT-374).
- Experimenter actions/types can't be reported in bitmaps (EXT-376).
- Clarify action bad argument errors (EXT-393).
- Many small clarifications, implementation defined features (EXT-395).
- Clarify that actions in a buckets always apply as an action-set (EXT-408).
- Merging action-set need to be set-field aware (EXT-409).
- Change action-list to list of actions for consistency (EXT-409).
- Introduce properly set of actions in the glossary (EXT-409).
- Clarify DSCP remark meter band (EXT-416).
- Add a section about pipeline consistency (EXT-415).
- Clarify handling of actions inconsistent with the match or packet (EXT-417).
- Clarify in-port and in-phy-port OXM field definitions (EXT-418).
- Clarify that OFPP\_CONTROLLER is a valid ingress port (EXT-418).
- Clarification on Flow Match Field length for experimenter fields with masks (EXT-420).
- Clarify handling of duplicate action in a write-action instruction or group bucket, allow either to return an error or filter duplicate actions (EXT-421).
- Clarify error code for Clear-Actions instruction with non-empty set of actions (EXT-422).
- Clarify error on unsupported OXM\_CLASS and OXM\_FIELD (EXT-423).
- Add section about reserved property/TLV types (EXT-429).
- Clarify meaning of OFPG\_ANY for watching group in group bucket (EXT-431).
- Separate pipeline field definitions from header field definitions (EXT-432).
- Clarify presence of header fields in Packet-In OXM list (EXT-432).
- Barrier reply must be generated when no pending request (EXT-433).
- Clarify error code for unsupported actions (EXT-434).
- Clarify error codes when setting table features is not supported or enabled (EXT-436).
- Port description must include all standard port, regardless of config or state (EXT-437).
- Improve channel reconnection recommendations (EXT-439).
- Wrong prefix, fix OFPPFL NO PACKET IN into OFPPC NO PACKET IN (EXT-443).
- Specify properly packet data field in packet-in and packet-out, especially CRCs (EXT-452).
- Specify how tunnel-id interract with logical ports, especially in output (EXT-453).
- More precise description of Tunnel ID pipeline field (EXT-453).
- Various typos, grammar and spelling fixes (EXT-455).

### B.16 OpenFlow version 1.4.0

Release date: August 5, 2013

Protocol version: 0x05

Please refers to the bug tracking ID for more details on each change.

#### B.16.1 More extensible wire protocol

The OpenFlow protocol was initially designed with many static fixed structures and limited extensibility. The introduction of the OpenFlow Extensible Match (OXM) in version 1.2 added much needed extensibility in the OpenFlow classifier. In version 1.4, many other parts of the protocol have been retrofitted with TLV structures for improved extensibility (EXT-262).

This TLV work affected many areas of the protocol. New TLVs have been added in previously fixed structures in the form of properties at the end of the structure. In some areas, the existing TLVs have been changed to use the common property TLV format. TLVs rules have been clarified. This additional extensibility of the protocol will allow a much easier way to add new features to the protocol in the future, and also greatly extend the Experimenter Extension API.

- Port structures: add port description properties, add port mod properties and add port stats properties.
- Table structures: add table mod properties, add table descriptions multipart, add table status asynchronous message.
- Queue structures: migrate queue description to multipart, convert queue description properties to standardised TLVs, add queue stats properties.
- Set-async structures: convert set-async-config to TLVs, add set-async experimenter property.
- Instruction structures: clarify instruction TLVs.
- Actions structures: clarify actions TLVs.
- Experimented structures: clarify experimenter TLVs.
- Properties errors: add a set of unified error codes for all properties.

### B.16.2 More descriptive reasons for packet-in

The OpenFlow pipeline saw extensive changes since 1.0, however, the reason values in the ofp\_packet\_in messages did not change. As a result, many distinct parts of the pipeline are using the same reason value. Version 1.4 introduces more descriptive reasons, so that the controller can properly distinguish which part of the pipeline redirected the packet to the controller (EXT-136).

The main change is that the "output action" reason OFPR\_ACTION is effectively split into four reasons, "apply-action", "action-set", "group bucket" and "packet-out", representing the four distinct context where this action is used. The "no match" reason OFPR\_NO\_MATCH is renamed to properly reflect the fact that it is generated by the table miss flow entry.

The new set of reason values for ofp\_packet\_in message is :

- OFPR\_TABLE\_MISS: No matching flow (table-miss flow entry).
- OFPR\_APPLY\_ACTION: Output to controller in apply-actions.
- OFPR INVALID TTL: Packet has invalid TTL.
- OFPR\_ACTION\_SET: Output to controller in action set.
- OFPR GROUP: Output to controller in group bucket.
- OFPR\_PACKET\_OUT: Output to controller in packet-out.

#### **B.16.3** Optical port properties

A new set of port properties add support for Optical ports, they include fields to configure and monitor the transmit and receive frequency of a laser, as well as its power (EXT-154). Those new properties can be used to configure and monitor either Ethernet optical port or optical ports on circuit switches.

- Optical port mod property ofp\_port\_mod\_prop\_optical to configure optical ports.
- Optical port stats property ofp\_port\_stats\_prop\_optical to monitor optical ports.

Optical port description property ofp\_port\_desc\_prop\_optical to describe optical port capabilities.

#### B.16.4 Flow-removed reason for meter delete

Add a new reason value OFPRR\_METER\_DELETE for the ofp\_flow\_removed message to denote that the flow entry was removed as a result of a meter deletion (EXT-261).

When a meter is deleted on the switch, all the flow entries that use that meter are removed. This is similar to how group operates. The flow that are removed may generate a flow-removed message (depending on config). In version 1.3, we did not have a reason for this condition, version 1.4 fixes that bug.

### **B.16.5** Flow monitoring

The OpenFlow protocol defines a multi-controller scheme where multiple controller can manage a switch. Flow monitoring allows a controller to monitor in real time the changes to any subsets of the flow table done by other controllers (EXT-187).

The flow monitoring framework allows a controller to define a number of monitors, each selecting a subset of the flow tables. Each monitor includes a table id and a match pattern that defines the subset monitored. When any flow entry is added, modified or removed in one of the subset defined by a flow monitor, an event is sent to the controller to inform it of the change.

- Multipart request ofp\_flow\_monitor\_request to set flow monitors on the switch.
- Flow monitor update events sent to controller, with full details using ofp\_flow\_update\_full or abbreviated using ofp\_flow\_update\_abbrev.
- Monitor flags to define the format of the updates.
- Flow control mechanism to avoid backlog of monitor updates.

### B.16.6 Role status events

Version 1.2 of the specification added the ability for a controller to set its role in a multi-controller environment. When a controller elected itself to "master" role, the previous master controller is demoted to "slave" role, however that controller was not informed about it. In version 1.4, the Role Status message enable the switch to inform a controller about change to its role (EXT-191).

- Role status event OFPT\_ROLE\_STATUS to inform controller to change to role.
- Role status properties for experimenter data, ofp\_role\_prop\_experimenter.

### **B.16.7** Eviction

Most flow tables have finite capacity. In previous versions of the specification, when a flow table is full, new flow entries are not inserted in the flow table and an error is returned to the controller. However, reaching that point is pretty problematic, as the controller need time to operate on the flow table and this may cause a disruption of service. Eviction adds a mechanism enabling the switch to automatically eliminate entries of lower importance to make space for newer entries (EXT-192). This enables smoother degradation of behaviour when the table is full.

- Table-mod flag OFPTC\_EVICTION to enable or disable eviction on a table.
- Flow-mod importance to optionally denote the importance of a flow entry for eviction.
- Table-desc eviction property ofp\_table\_mod\_prop\_eviction to describe the type of eviction performed by the switch.

# **B.16.8** Vacancy events

Most flow tables have finite capacity. In previous versions of the specification, when a flow table is full, new flow entries are not inserted in the flow table and an error is returned to the controller. However, reaching that point is pretty problematic, as the controller need time to operate on the flow table and this may cause a disruption of service. Vacancy events adds a mechanism enabling the controller to get an early warning based on a capacity threshold chosen by the controller (EXT-192). This allows the controller to react in advance and avoid getting the table full.

- Table status event OFPT\_TABLE\_STATUS with reasons OFPTR\_VACANCY\_DOWN and OFPTR\_VACANCY\_UP to inform controller of vacancy change.
- Hysteresis mechanism to avoid spurious events using two threshold, vacancy\_down and vacancy\_up.
- Table-mod vacancy property to set vacancy thresholds, ofp\_table\_mod\_prop\_vacancy.

#### B.16.9 Bundles

Add the bundle mechanism, enabling to apply a group of OpenFlow message as a single operation (EXT-230). This enables the quasi-atomic application of related changes, and to better synchronise changes across a series of switches.

- Bundle control message OFPT\_BUNDLE\_CONTROL to create, destroy and commit bundles.
- Bundle add message OFPT BUNDLE ADD MESSAGE to add an OpenFlow message into a bundle.
- Bundle error type OFPET\_BUNDLE\_FAILED to report bundle operation errors.

### B.16.10 Synchronised tables

Many switches can perform multiple lookups on the same lookup data. For example, a standard Ethernet learning table performs a learning lookup and a forwarding lookup on the same set of MAC addresses. Another example is RPF checks which reuses the IP forwarding data. The synchronised table feature enables to represent those constructs as a set of two tables which data is synchronised (EXT-232).

Synchronised table is expressed using a new property in the table feature, OFPTFPT\_TABLE\_SYNC\_FROM. It defines the synchronisation abstraction between the two flow tables, however it does not define and express the flow entry transformation between the flow tables.

# **B.16.11** Group and Meter change notifications

The OpenFlow protocol defines a multi-controller scheme where multiple controller can manage a switch. Group and Meter change notifications allow a controller to monitor in real time the changes to the group table or meter table done by other controllers (EXT-235).

The "group-mod" and "meter-mod" requests are simply encapsulated in a OFPT\_REQUESTFORWARD asynchronous message sent to other controllers. Those notifications are enabled and disabled via the "set-async-config" message.

#### B.16.12 Error code for bad priority

Some switches may have restrictions on the priorities that can be used in a table. For example a switch may be enforcing some "longest prefix match" rule in a table, requiring the priority to be related to the mask. A new error code, OFPFMFC\_BAD\_PRIORITY, enables the switch to properly inform the controller when this happens (EXT-236).

#### B.16.13 Error code for Set-async-config

The OFPT\_GET\_ASYNC\_REQUEST feature was introduced in version 1.3.0. There was no error messages defined for that features, however it is possible for this request to fail. A new error type, OFPET\_ASYNC\_CONFIG\_FAILED, which appropriate code, enables the switch to properly inform the controller when this happens (EXT-237).

The set of error codes defined for OFPET ASYNC CONFIG FAILED are:

- OFPACFC\_INVALID: One mask is invalid.
- OFPACEC UNSUPPORTED: Requested configuration not supported.
- OFPACFC\_EPERM: Permissions error.

#### B.16.14 PBB UCA header field

A new OXM field OFPXMT\_OFB\_PBB\_UCA has been added to match the "use customer address" header field from the PBB header (EXT-256).

#### B.16.15 Error code for duplicate instruction

The OpenFlow specification defines the instructions included in a flow entry as a set, and that an instruction can not be duplicated in that set. A new error code, OFPBIC\_DUP\_INST, enables the switch to properly inform the controller when flow entries contain duplicate instructions (EXT-260).

#### B.16.16 Error code for multipart timeout

Multipart request and replies are encoded as a sequence of messages. This version of the specification defines how to deal with unterminated sequence, some minimum timeout are defined as well as error codes (EXT-264).

- Define minimum timeout (100 ms) and error code (OFPBRC\_MULTIPART\_REQUEST\_TIMEOUT) for unterminated multipart request sequences.
- Define minimum timeout (1 s) and error code (OFPBRC\_MULTIPART\_REPLY\_TIMEOUT) for unterminated multipart reply sequences.

### B.16.17 Change default TCP port to 6653

IANA allocated to ONF the TCP port number 6653 to be used by the OpenFlow switch protocol. All uses of the previous port numbers, 6633 and 976, should be discontinued. OpenFlow switches and OpenFlow controllers must use 6653 by default (when not using a user specified port number).

# B.17 OpenFlow version 1.4.1-alpha1

Release date: Internal revision, never released.

Protocol version: 0x05

Please refers to the bug tracking ID for more details on each change.

#### B.17.1 Changes

- When adding a flow entry due to synchronisation, overwrite and existing entry instead of merging them (EXT-355).
- Extend the scope of the overlap checking flag to the synchronised flow table (EXT-355).
- Mandate reversible translation for bidirectional synchronised tables (EXT-361).
- Add synchronisation error OFPFMFC IS SYNC (EXT-378).
- Add capabilities in switch features for bundles and flow monitoring (EXT-404).

### **B.17.2** Clarifications

- Clarify that a table can synchronise on itself (EXT-346).
- Clarify that the vacancy property is optional in table-mods (EXT-346).
- Fix typo, replace OFPFMF\_OWN with OFPFMF\_NO\_ABBREV in flow monitoring section (EXT-346).
- Fix mistake, Send error if bundled message have the same xid, not the reverse (EXT-346).
- Clarify that bundles can't be applied on different switches exactly at the same time, only approximately (EXT-355).
- Clarify that if the synchronised flow entry does not exist, no flow entry is removed (EXT-355).
- Clarify learning example in synchronisation section, and clarify that it is only illustrative (EXT-355).
- Recommend against complex table synchronisation (EXT-361).
- Clarify that the flow monitor reply message may be an asynchronous message (EXT-371).

- Clarify usage of synchronisation error OFPFMFC CANT SYNC (EXT-378).
- Clarify that Bundle is optional (EXT-404).
- Clarify that Flow monitoring is optional (EXT-404).
- Add description for duplicate instruction error OFPBIC\_DUP\_INST (EXT-424).
- Various typos, grammar and spelling fixes (EXT-346, EXT-355).

### B.18 OpenFlow version 1.5.0

Release date: December, 2014

Protocol version: 0x06

Please refers to the bug tracking ID for more details on each change.

### **B.18.1** Egress Tables

In previous versions of the specification, all processing was done in the context of the input port. Version 1.5 introduces Egress Tables, enabling processing to be done in the context of the output port (EXT-306). When a packet is output to a port, it will start processing at the first egress table where flow entries can define processing and redirect the packet to other egress tables. A new OXM field, OXM\_OF\_ACTSET\_OUTPUT, enable egress flow entry to match the outgoing port (EXT-233).

- Packet sent to an output port is processed by the first egress table.
- Group processing and reserved port substitution happen before egress tables.
- Define behaviour of egress table and egress flow entries, mostly similar to ingress.
- New match field OXM\_OF\_ACTSET\_OUTPUT to match output value from action-set, mandatory for egress tables, optional for ingress tables.
- Forbid adding output or group action in the egress action-set to prevent changing output port.
- Allow egress flow entry to use output action in action list for egress mirroring.
- Pipeline fields are carried from ingress to egress tables.
- Table Feature capabilities to set the first egress table.
- Table Feature capabilities to identify table than can be used for ingress and/or egress.
- Introduce table feature request commands for simpler table features updates.

#### B.18.2 Packet Type aware pipeline

In previous versions of the specification, all packets must be Ethernet packets. Version 1.5 introduces a packet aware pipeline, enabling processing of other types of packets, such as IP packets or PPP packets (EXT-112). A new OXM pipeline field identifies the packet type. The packet type is defined in an extensible manner, it uses multiple namespaces defined by other standard and allow experimenter packet types. The packet type field can be used in matches and acts as a prerequisite for header fields. The packet type field can also be used in packet-in and packet-out messages to identify the payload carried by those messages.

- Header Type definition based on various existing namespaces, define Canonical Header Types.
- New Packet Type pipeline field. This OXM contains the Canonical Header Type of the packet outermost header.

- Packet Type OXM can be used in match to match specific packet types.
- Packet Type OXM used as prerequisite for various header match fields.
- Packet Type OXM used in packet-in to identify the payload.
- Packet Type OXM used in packet-out to identify the payload.
- Table Feature property expose the packet types supported by each flow table.

The specification is currently restricted to a single packet type per switch because packet type conversions are not defined.

### **B.18.3** Extensible Flow Entry Statistics

Previous versions of the specification use a fixed structure for flow entry statistics. Version 1.5 introduces a flexible encoding, OpenFlow eXtensible Statistics (OXS), to encode any arbitrary flow entry statistics (EXT-334). Existing flow entry statistics are redefined as standard OXS fields.

- OXS TLV format to express flow entry statistics, based on OXM and compatible with OXM for simpler implementation.
- Express existing flow entry statistics as standard OXS fields : flow duration, flow count, packet count, byte count.
- Introduce new standard flow entry statistic : flow idle time.
- Enable arbitrary class based or experimenter based flow entry statistics.
- Use OXS in all messages carrying flow entry statistics: flow removed message, flow statistics multipart, flow aggregate mutipart.
- Introduce lightweight flow statistics multipart, rename existing flow statistics as flow description.

### **B.18.4** Flow Entry Statistics Trigger

Polling flow entry statistics can induce high overhead and utilisation for the switch. A new statistics trigger mechanism enable statistics to be automatically sent to the controller based on various statistics thresholds (EXT-335).

- New instruction OFPIT\_STAT\_TRIGGER to define a set of statistics thresholds using OXS.
- Statistics trigger flags to allow periodic thresholds.
- Efficient batching of statistics threshold to the controller using the lightweight flow statistics multipart.

#### B.18.5 Copy-Field action to copy between two OXM fields

The existing Set-Field action allows to set a header field or pipeline field with a static value. The new Copy-Field action allows to copy the value from one header or pipeline field into another header or pipeline field (EXT-320).

- New instruction OFPAT\_COPY\_FIELD to copy value between fields.
- Source and destination fields defined as OXM IDs, support standard OXMs, class based OXMs and experimenter OXMs.
- The Copy-Field instruction can copy bit sub-fields of any length from source to destination at any offset.

• New Table Features property to express support for Copy-Field.

### B.18.6 Packet Register pipeline fields

Introduce Packet Registers, a set pipeline fields that can be used as generic scratch space for the *Copy-Field* action (EXT-244). The packet register are optionally matchable.

- New OXM class for Packet Registers pipeline fields.
- Switch can support as many register as it wants, each register is 64 bits.

# B.18.7 TCP flags matching

A new OXM field OFPXMT\_OFB\_TCP\_FLAGS has been added to match the flag bits in the TCP header (EXT-109). This field allow to match all flags, such as SYN, ACK and FIN, and may be used to detect the start and the end of TCP connections.

### B.18.8 Group command for selective bucket operation

In previous versions of the specification, group operation can only change the entire set of group buckets in a group. Two new group commands enable to insert or remove specific group buckets without impacting the other group buckets in the group (EXT-350).

- Group command OFPGC\_INSERT\_BUCKET to insert individual group buckets into a group.
- Group command OFPGC\_REMOVE\_BUCKET to remove specific group buckets from a group.
- Add bucket\_id field to buckets to identify buckets.
- Add group property to extend groups.
- Add group bucket properties to extend group buckets.
- Redefine bucket fields weight, watch\_port and watch\_group as group bucket properties.

#### B.18.9 Allow set-field action to set metadata field

Previous versions of the specification had a restriction on the set-field action, the pipeline field OXM\_OF\_METADATA could not be a valid argument for the set-field action. In this specification, the restriction is removed and OXM\_OF\_METADATA can be a valid argument for the set-field action (EXT-46).

#### B.18.10 Allow wildcard to be used in set-field action

In previous version of the specification, the *Set-Field* action could only set the entire field referenced. This version of the specification enable the switch to support mask in Set-Field, so that only the specified bits of the field are modified (EXT-314).

### **B.18.11 Scheduled Bundles**

The previous version of the specification introduced *bundle messages*. A bundle is a sequence of Open-Flow modification requests from the controller that is applied as a single Open-Flow operation.

The current specification extends the bundle feature (EXT-340), allowing:

- Scheduled bundles: a bundle commit message may include an *execution time*, specifying *when* the switch is expected to commit the bundle.
- Bundle features request: allows a controller to query a switch about its bundle capabilities, including whether it supports atomic bundles, ordered bundles, and scheduled bundles.

#### **B.18.12** Controller connection status

The Controller Connection Status enable controller to know the status of all the connections from the switch to controllers (EXT-454). This allow a controller to detect control network partitioning or monitor the status of other controllers. Controllers are identified using a standard URI (EXT-275).

- Controller status multipart messages to query status of controller connections.
- Define URI scheme to identify controller connections.
- Enable controller to set a short id to identify themselves.
- Controller status message to inform controller of changes in connection status.

### B.18.13 Meter action

In previous versions of the specification, metering was done through a Meter instruction. This version replaces this with a Meter action (EXT-379). As the result, multiple meters can be attached to a flow entry, and meters can be used in group buckets.

- Introduce Meter action OFPAT\_METER.
- Deprecate Meter instruction OFPIT\_METER.

#### B.18.14 Enable setting all pipeline fields in packet-out

Previous versions of the specification support setting the *In-Port* pipeline field of the packet in the *Packet-Out* message. This version of the specification supports setting all pipeline field of the packet in the *Packet-Out* message (EXT-427). This enable, for example, to set the tunnel-id pipeline field for the logical port.

- Add match structure in packet\_out messages to encode pipeline fields as OXMs.
- Move the in port field as an OXM in the match.
- Specify that packet-out set the pipeline fields of the packet based on fields included in the match.

### B.18.15 Port properties for pipeline fields

Logical ports may consume and generate pipeline fields. For example, the pipeline field *Tunnel ID* can be used by a logical port to express the metadata associated with a encapsulation. New port properties allow logical ports to express which pipeline fields are consumed and which are produced by the logical port (EXT-388).

- Port description property OFPPDPT\_PIPELINE\_INPUT is the list of OXM fields provided for packet received on that port.
- Port description property OFPPDPT\_PIPELINE\_OUTPUT is the list of pipeline fields that are consumed by the port when packets are sent to it.

# B.18.16 Port property for recirculation

Logical ports may recirculate packets back to the OpenFlow pipeline after having processed them. A new property allow a port to associate another port where packets are returned to the OpenFlow pipeline (EXT-399). Such recirculation may preserve pipeline fields.

# B.18.17 Clarify and improve barrier

The description of the barrier message and its effect on the switch was unified throughout the specification and clarified (EXT-189). Barrier also are changed to commit state to the datapath.

- Clarify that barrier control message ordering.
- Clarify that barrier notify of completed processing.
- Specify that barrier commit state to datapath.
- Clarify that ordered bundles can be use as an alternative to barriers.

#### B.18.18 Always generate port status on port config change

In previous versions of the specification, the port status message was sent to the controllers only in case the port state changed or if the configuration was changed outside OpenFlow. On the other hand, if one controller changed the configuration, no port status message was sent to the controllers. This is problematic in multi-controller setup, as other controller can't be notified of port configuration changes done by one controller.

In this specification, the port status message is sent to the controllers for any change of the port configuration, including those done by one OpenFlow controller (EXT-338).

### B.18.19 Make all Experimenter OXM-IDs 64 bits

Previous versions of the specification were unclear on how to encode Experimenter OXMs. This specification mandates that Experimenter OXMs encode the experimenter type in the oxm\_field field of the OXM header (EXT-380). This enable all OXM-IDs used to identified OXMs to be uniformly 64 bits.

#### B.18.20 Unified requests for group, port and queue multiparts

The multipart requests for statistics and descriptions have been changed to using a common structure in the case of group, port and queue (EXT-69).

- Port statistics and port descriptions use a common request format.
- Individual port descriptions can be requested.
- Group statistics and group descriptions use a common request format.
- Individual group descriptions can be requested.
- Queue statistics and queue descriptions use a common request format.

#### B.18.21 Rename some type for consistency

Some OpenFlow types were renamed for consistency.

- Statistics multiparts now have the \_STATS suffix (EXT-302).
- Multipart METER\_CONFIG was renamed to METER\_DESC (EXT-302).
- Meter statistics field flow\_count was renamed to ref\_count (EXT-374).

### **B.18.22** Specification reorganisation

Some text was moved in the specification to improve readability and make more accurate cross references (EXT-507).

- Add paragraph headings for error codes.
- Move specification of error conditions to the error message section.
- Move group and meters at the end of the OpenFlow table section.
- Move subsection about flow removal into section about control channel.
- Move Multipart tables subsections further down in multipart section.
- Add paragraph headings for action structures.

# Appendix C Credits

Spec contributions, in alphabetical order:

Anders Nygren, Ben Pfaff, Bob Lantz, Brandon Heller, Casey Barker, Curt Beckmann, Dan Cohn, Dan Malek, Dan Talayco, David Erickson, David McDysan, David Ward, Edward Crabbe, Fabian Schneider, Glen Gibb, Guido Appenzeller, Jean Tourrilhes, Johann Tonsing, Justin Pettit, KK Yap, Leon Poutievski, Linda Dunbar, Lorenzo Vicisano, Martin Casado, Masahiko Takahashi, Masayoshi Kobayashi, Michael Orr, Navindra Yadav, Nick McKeown, Nico dHeureuse, Peter Balland, Rajesh Madabushi, Rajiv Ramanathan, Reid Price, Rob Sherwood, Saurav Das, Shashidhar Gandham, Spike Curtis, Tal Mizrahi, Tatsuya Yabe, Wanfu Ding, Yiannis Yiakoumis, Yoram Moses, Zoltán Lajos Kis.
